ENCYCLOPÆDIA BRITANNICA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a PLAN,

BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digested into the FORM of Distinct
TREATISES OR SYSTEMS,
COMPREHENDING
The HISTORY, THEORY, and PRACTICE, of each,
according to the Latest Discoveries and Improvements;

AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS,
MANNERS, and the OECONOMY of LIFE:

TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General HISTORY, Ancient and Modern, of the different Empires, Kingdoms, and States;
AND
An Account of the LIVES of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best Authors, in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Translations, Journals, and Memoirs, of Learned Societies, both at home and abroad; the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE THIRD EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. X.

INDUCTI DISCANT, ET AMENŒ MEMINISSE PERIT.

EDINBURGH,
PRINTED FOR A. BELL AND C. MACFARQUHAR,
MDCCLXXVII.

Entered in Stationers Hall in Terms of the Act of Parliament.

ENCYCLOPÆDIA BRITANNICA.

L E S

^{Lestoff, L. Estrange.} **LESTOFF**, or **LESTOFF**, a town of Suffolk in England, seated on the sea-shore, 117 miles north-west of London. It is concerned in the fisheries of the North-sea, cod, herrings, mackerels, and sprats; has a church, and a dissenting meeting-house; and for its security, six eighteen-pounders, which they can move as occasion requires; but it has no battery. The town consists of 500 houses; but the streets, though tolerably paved, are narrow. It has a market on Wednesdays, and two fairs in the year for petty chapmen. The coast is there very dangerous for strangers.

L'ESTRANGE (Sir Roger), a noted writer in the 17th century, was descended from an ancient family, seated at Hunstanton-hall in the county of Norfolk, where he was born in 1616, being the youngest son of Sir Hammond L'Estrange baronet, a zealous royalist. Having in 1644 obtained a commission from King Charles I. for reducing Lynn in Norfolk, then in possession of the parliament, his design was discovered, and his person seized. He was tried by a court martial at Guildhall in London, and condemned to die as a spy; but was reprieved, and continued in Newgate for some time. He afterward went beyond sea; and in August 1653 returned to England, where he applied himself to the protector Oliver Cromwell, and having once played before him on the bass-viol, he was by some nicknamed *Oliver's fiddler*. Being a man of parts, master of an easy humorous style, but withal in narrow circumstances, he set up a newspaper, under the title of *The Public Intelligence*, in 1663; but which he laid down, upon the publication of the first London gazette in 1665, having been allowed, however, a consideration by government. Some time after the Popish plot, when the Tories began to gain the ascendant over the Whigs, he, in a paper called the *Observer*, became a zealous champion for the former. He was afterwards knighted, and served in the parliament called by King James II. in 1685. But things taking a different turn in that prince's reign, in point of liberty of conscience, from what most people expected, our author's *Observers* were disused as not at all suiting the times. However, he continued licensor of the press till King William's accession, in whose reign he met with some trouble as a dissipated person. However, he went to his grave in peace, after he had in a manner surived his intellectuals. He published a great many political tracts, and translated several works from the Greek, Latin, and Spanish; viz. Josephus's works, Cicero's Offices, Seneca's Morals, Erasmus's Colloquies, Æsop's Fables, and Bonas's Guide to Eternity. The character of his style has been variously represented; his language being observed by

Vol. X. Part I.

L E T

some to be easy and humorous, while Mr Gordon says, ^{Lestweithel, Lethargy.} "that his productions are not fit to be read by any who have taste or good-breeding. They are full of phrases picked up in the streets, and nothing can be more low or nauseous."

LESTWEITHEL, a town of Cornwall in England, about 229 miles distant from London. It is a well-built town, where are kept the common gaol, the weights and measures for the whole stannary, and the county courts. It stands on the river Foy, which brought up vessels from Fowey, before it was choaked up with sand coming from the tin-mines, and therefore its once flourishing trade is decayed; but it holds the buhelage of coals, salt, malt, and corn, in the town of Fowey, as it does the anchorage in its harbour. It was made a corporation by Richard earl of Cornwall when he was king of the Romans, and has had other charters since. It consists of seven capital burgesses (whereof one is a mayor), and 17 assistants or common council. It is part of the duchy of Cornwall, to which it pays L. 11 : 19 : 10 a year for its liberties. Its chief trade is the woollen manufactory. Its church has a spire, the only one except that of Helston in the county. Its market is Friday, and its fairs are three. It first returned members to parliament in the 33d of Edward I. They are chosen by their burgesses and assistants. It was anciently the shire-town, and the knights of the shire are still chosen here.

LETLCHLADE, a town of Gloucestershire, 90 miles from London, on the borders of Oxfordshire and Berks, and the great road to Gloucester; had anciently a nunnery, and a priory of black canons. In this parish is Clay-hill. The market is on Tuesday; and it has two fairs. It is supposed to have been a Roman town: for a plain Roman road runs from hence to Cirencester; and by digging in a meadow near it some years ago, an old building was discovered, supposed to be a Roman bath, which was 50 feet long, 40 broad, and 4 high, supported with 100 brick pillars, curiously inlaid with stones of divers colours of tesseraic work. The Leech, the Coln, the Churn, and Isis, which all rise in the Cotswould-hill, join here in one full stream, and become one river, called the *Thames*, which begins here to be navigable, and barges take in butter, cheese, and other goods, at its quay for London.

LETHARGY, in medicine (from *λεθη* oblivion, and *αργεια* numbness, *lusingis*), a disease consisting of a profound drowsiness or sleepiness, from which the patient can scarce be awaked; or, if awaked, he remains stupid, without sense or memory, and presently sinks again into his former sleep. See *MEDICINE-Index*.

LETHARGY, in fariery. See there, § 9.

A

LETHE,

Lethe
||
Letter.

Letter.

LETHE, in the ancient mythology, one of the rivers of hell, signifying oblivion or forgetfulness; its waters extend, according to poetic fiction, the peculiar quality of making those who drank them forget every thing that was past.

LETI (Gregorio), an eminent Italian writer, was descended of a family which once made a considerable figure at Bologna: Jerom, his father, was page to prince Charles de Medicis; served some time in the troops of the grand duke as captain of foot; and settling at Milan, married there in 1628. He was afterward governor of Almontea in Calabria, and died at Salerno in 1639. Our author was born at Milan in 1630, studied under the Jesuits at Cosenza, and was afterward sent by an uncle to Rome, who would have him enter into the church; but he being averse to it, went into Geneva, where he studied the government and the religion there. Thence he went to Lausanne; and contracting an acquaintance with John Anthony Guerin, an eminent physician, lodged at his house, made profession of the Calvinist religion, and married his daughter. He settled at Geneva; where he spent almost twenty years, carrying on a correspondence with learned men, especially those of Italy. Some contests obliged him to leave that city in 1679; upon which he went to France, and then into England, where he was received with great civility by Charles II. who, after his first audience, made him a present of a thousand crowns, with a promise of the place of historiographer. He wrote there the History of England; but that work not pleasing the court on account of his too great liberty in writing, he was ordered to leave the kingdom. He went to Amsterdam in 1682, and was honoured with the place of historiographer to that city. He died suddenly in 1701. He was a man of indefatigable application, as the multiplicity of his works show. The principal of these are, 1. The universal monarchy of Louis XIV. 2. The life of Pope Sixtus V. 3. The life of Philip II. king of Spain. 4. The life of the emperor Charles V. 5. The life of Elizabeth, queen of England. 6. The history of Oliver Cromwell. 7. The history of Great Britain, 5 vols 12mo. 8. The history of Geneva, &c.

LETRIM, a county of Ireland, in the province of Connaught, 44 miles in length and 17 in breadth; bounded on the east and north-east by Cavan and Fermanagh, by Sligo and Roscommon on the west and south-west, and by Longford on the east and south-east. It is a hilly country, with rank grass, which feeds a great number of cattle. The chief town is Letrim, seated not far from the river Shannon. It contains 4000 houses, 21 parishes, 5 baronies, 2 boroughs, and sends 6 members to parliament.

LETTER, a character used to express one of the simple sounds of the voice; and as the different simple sounds are expressed by different letters, these, by being differently compounded, become the visible signs or characters of all the modulations and mixtures of sounds used to express our ideas in a regular language; (See LANGUAGE). Thus, as by the help of speech we render our ideas audible; by the assistance of letters we render them visible, and by their help we can wrap up our thoughts, and send them to the most distant parts of the earth, and read the transactions of different ages. As to the first letters, what they were, who first in-

vented them, and among what people they were first in use, there is still room to doubt: Philo attributes this great and noble invention to Abraham; Josephus, St Irenæus, and others, to Enoch; Bibliander, to Adam; Eusebius, Clemens Alexandrinus, Cornelius Agrippa, and others, to Moses; Pomponius Mela, Herodian, Rufus Festus, Pliny, Lucan, &c. to the Phœnicians; St Cyprian, to Saturn; Tacitus, to the Egyptians; some, to the Ethiopians; and others, to the Chinese: but, with respect to these last, they can never be intitled to this honour, since all their characters are the signs of words, formed without the use of letters; which renders it impossible to read and write their language without a vast expence of time and trouble; and absolutely impossible to print it by the help of types, or any other manner but by engraving, or cutting in wood. See PRINTING.

There have been also various conjectures about the different kinds of letters used in different languages: thus, according to Crinitus, Moses invented the Hebrew letters; Abraham, the Syriac and Chaldee; the Phœnicians, those of Attica, brought into Greece by Cadmus, and from thence into Italy by the Pelasgians; Nicotratra, the Roman; Isis, the Egyptian; and Vulfilas, those of the Goths.

It is probable, that the Egyptian hieroglyphics were the first manner of writing: but whether Cadmus and the Phœnicians learned the use of letters from the Egyptians, or from their neighbours of Judea or Samaria, is a question; for since some of the books of the Old Testament were then written, they are more likely to have given them the hint, than the hieroglyphics of Egypt. But wheresoever the Phœnicians learned this art, it is generally agreed, that Cadmus the son of Agenor first brought letters into Greece; whence, in following ages, they spread over the rest of Europe. See ALPHABET and WRITING.

Letters make the first part or elements of grammar; an assemblage of these compose syllables and words, and these compose sentences. The alphabet of every language consists of a number of letters, which ought each to have a different sound, figure, and use. As the difference of articulate sounds was intended to express the different ideas of the mind, so one letter was originally intended to signify only one sound, and not, as at present, to express sometimes one sound and sometimes another; which practice has brought a great deal of confusion into the languages, and rendered the learning of the modern tongues much more difficult than it would otherwise have been. This consideration, together with the deficiency of all the known alphabets, from their wanting some letters to express certain sounds, has occasioned several attempts towards an universal alphabet, to contain an enumeration of all such single sounds or letters as are used in any language. See ALPHABET.

Grammarians distinguish letters into vowels, consonants, mutes, liquids, diphthongs, and characteristics. They are likewise divided into capital and small letters. They are also denominated from the shape and turn of the letters; and in writing are distinguished into different hands, as round-text, German-text, round-hand, Italian, &c. and in printing, into Roman, Italic, and black letter.

The term LETTER, or Type, among printers, not on-

Letter. ly includes the CAPITALS, SMALL CAPITALS, and small letters, but all the points, figures, and other marks cast and used in printing; and also the large ornamental letters, cut in wood or metal, which take place of the illuminated letters used in manuscripts. The letters used in printing are cast at the ends of small pieces of metal, about three quarters of an inch in length; and the letter being not indented, but raised, easily gives the impression, when, after being blacked with a glutinous ink, paper is closely pressed upon it. See the articles PRINTING and TYPE. A fount of letters includes small letters, capitals, small capitals, points, figures, spaces, &c.; but besides, they have different kinds of two-line letters, only used for titles, and the beginning of books, chapters, &c. See FOUNT.

LETTER is also a writing addressed and sent to a person. See EPISTLE.

The art of epistolary writing, as the late translator of Pliny's Letters has observed, was esteemed by the Romans in the number of liberal and polite accomplishments; and we find Cicero mentioning with great pleasure, in some of his letters to Atticus, the elegant specimen he had received from his son of his genius in this way. It seems indeed to have formed part of their education; and, in the opinion of Mr Locke, it well deserves to have a share in ours. "The writing of letters (as that judicious author observes) enters so much into all the occasions of life, that no gentleman can avoid shewing himself in compositions of this kind. Occurrences will daily force him to make this use of his pen, which lays open his breeding, his sense, and his abilities, to a severer examination than any oral discourse." It is to be wondered we have so few writers in our own language who deserve to be pointed out as models upon such an occasion. After having named Sir William Temple, it would perhaps be difficult to add a second. The elegant writer of Cowley's life mentions him as excelling in this uncommon talent; but as that author declares himself of opinion, "That letters which pass between familiar friends, if they are written as they should be, can scarce ever be fit to see the light," the world is deprived of what no doubt would have been well worth its inspection. A late distinguished genius treats the very attempt as ridiculous, and professes himself "a mortal enemy to what they call a fine letter." His aversion however was not so strong, but he knew to conquer it when he thought proper; and the letter which closes his correspondence with bishop Atterbury is, perhaps, the most genteel and manly address that ever was penned to a friend in disgrace. The truth is, a fine letter does not consist in saying fine things, but in expressing ordinary ones in an uncommon manner. It is the *proprie communia dicere*, the art of giving grace and elegance to familiar occurrences, that constitutes the merit of this kind of writing. Mr Gay's letter, concerning the two lovers who were struck dead with the same flash of lightning, is a master-piece of the sort; and the specimen he has there given of his talents for this species of composition makes it much to be regretted we have not more from the same hand.

Ward's
Oratory.

Of the Style of Epistolary Composition. Purity in the choice of words, and justness of construction, joined with perspicuity, are the chief properties of this style.

Accordingly Cicero says: "In writing letters, we make use of common words and expressions." And Seneca more fully, "I would have my letters to be like my discourses, when we either sit or walk together, unstudied and easy." And what prudent man, in his common discourse, aims at bright and strong figures, beautiful turns of language, or laboured periods? Nor is it always requisite to attend to exact order and method. He that is master of what he writes, will naturally enough express his thought without perplexity and confusion; and more than this is seldom necessary, especially in familiar letters.

Indeed, as the subjects of epistles are exceedingly various, they will necessarily require some variety in the manner of expression. If the subject be something weighty and momentous, the language should be strong and solemn; in things of a lower nature, more free and easy; and upon lighter matters, jocose and pleasant. In exhortations, it ought to be lively and vigorous; in consolations, kind and compassionate; and in advising, grave and serious. In narratives, it should be clear and distinct; in requests, modest; in commendations, friendly; in prosperity cheerful, and mournful in adversity. In a word, the style ought to be accommodated to the particular nature of the thing about which it is conversant.

Besides, the different character of the person, to whom the letter is written, requires a like difference in the modes of expression. We do not use the same language to private persons, and those in a public station; to superiors, inferiors, and equals. Nor do we express ourselves alike to old men and young, to the grave and facetious, to courtiers and philosophers, to our friends and strangers. Superiors are to be addressed to with respect, inferiors with courtesy, and equals with civility; and every one's character, station, and circumstances in life, with the relation we stand in to him, occasions some variety in this respect. But when friends and acquaintances correspond by letters, it carries them into all the freedom and good-humour of conversation; and the nearer it resembles that, the better, since it is designed to supply the room of it. For when friends cannot enjoy each others company, the next satisfaction is to converse with each other by letters. Indeed, sometimes greater freedom is used in epistles, than the same persons would have taken in discoursing together; because, as Cicero says, "A letter does not blush." But still nothing ought to be said in a letter, which, considered in itself, would not have been fit to say in discourse; though modestly perhaps, or some other particular reason, might have prevented it. And thus it frequently happens in requests, reproofs, and other circumstances of life. A man can ask that by writing, which he could not do by words, if present; or blame what he thinks amiss in his friend with greater liberty when absent, than if they were together. From hence it is easy to judge of the fitness of any expression to stand in an epistle, only by considering, whether the same way of speaking would be proper in talking with the same person. Indeed, this difference may be allowed, that as persons have more time to think, when they write, than when they speak; a greater accuracy of language may sometimes be expected in one,

Letter,
Lettuce.

than the other. However, this makes no odds as to the kind of style; for every one would choose to speak as correctly as he writes, if he could. And therefore all such words and expressions, as are unbecoming in conversation, should be avoided in letters; and a manly simplicity free of all affectation, plain, but decent and agreeable, should run through the whole. This is the usual style of Cicero's epistles, in which the plainness and simplicity of his diction is accompanied with something so pleasant and engaging, that he keeps up the attention of his reader, without suffering him to tire. On the other hand, Pliny's style is fuscini and witty; but generally so full of turns and quibbles upon the sound of words, as apparently render it more stiff and affected than agrees with conversation, or than a man of sense would choose in discourse, were it in his power. You may in some measure judge of Pliny's manner, by one short letter to his friend, which runs thus: "How fare you? As I do in the country? pleasantly? that is, at leisure? For which reason I do not care to write long letters, but to read them; the one as the effect of niceness, and the other of idleness. For nothing is more idle than your nice folks, or curious than your idle ones. Farewell." Every sentence here consists of an antithesis, and a jingle of words, very different from the style of conversation, and plainly the effect of study. But this was owing to the age in which he lived, at which time the Roman eloquence was sunk into pins, and an affectation of wit; for he was otherwise a man of fine sense and great learning.

LETTER of Attorney, in law, is a writing by which one person authorises another to do some lawful act in his stead; as to give seizure of lands, to receive debts, sue a third person, &c.

The nature of this instrument is to transfer to the person to whom it is given, the whole power of the maker, to enable him to accomplish the act intended to be performed. It is either general or special: and sometimes it is made revocable, which is when a bare authority is only given; and sometimes it is irrevocable, as where debts, &c. are assigned from one person to another. It is generally held, that the power granted to the attorney must be strictly pursued; and that where it is made to three persons, two cannot execute it. In most cases, the power given by a letter of attorney determines upon the death of the person who gave it. No letter of attorney made by any seamen, &c. in any ship of war, or having letters of marque, or by their executors, &c. in order to empower any person to receive any share of prizes or bounty-money, shall be valid, unless the same be made revocable, and for the use of such seamen, and be signed and executed before, and attested by, the captain and one other of the signing officers of the ship, or the mayor or chief magistrate of some corporation.

LETTER of Mart or Marque. See *MARQUE*.

LETTERS Patent or Overt, are writings sealed with the great seal of England, whereby a man is authorised to do, or enjoy any thing, which, of himself, he could not do. See *PATENT*.—They are so called, by reason of their form; as being open, with the seal affixed, ready to be shown for the confirmation of the authority given by them.

LETTUCE, in botany. See *LACTUCA*.

Levant
Leucata.

LEVANT, in geography, signifies any country situated to the east of us, or in the eastern side of any continent or country, or that on which the sun rises.

LEVANT, is also a name given to the eastern part of the Mediterranean sea, bounded by Natolia or the Lesser Asia on the north, by Syria and Palestine on the east, by Egypt and Barca on the south, and by the island of Candia and the other part of the Mediterranean on the west.

LEVATOR, in anatomy, a name given to several muscles. See *ANATOMY*, *Table of the Muscles*.

LEUCA, in antiquity, a geographical measure of length in use among the later Gauls; which, according to Jornandes, who calls it *leuca*, contained fifteen hundred paces, or one mile and a half. Hence the name of *league*, now reckoned at three miles; in the lower age, called *leuca*.

LEUCADENDRON, in botany: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 48th order, *Aggregate*. The florets are tripetalous, with one petal of each trisid; the receptacle is a little villous; there is no proper calyx; the anthers are almost coalited.

LEUCADIA, formerly called *Neritis*, a peninsula of Acarnania, (Homer); but afterwards, by cutting through the peninsula, made an island, as it is at this day, called *St Maura*.

LEUCAS, (anc. geog.), formerly called *Neritos* and *Neritus*, a town of Leucadia or Leucas; situated near a narrow neck of land, or isthmus, on a hill facing the east and Acarnania: the foot or lower part of the town was a plain lying on the sea by which Leucadia was divided from Acarnania, (Livy); though Thucydides places Leucas more inward in the island, which was joined to the continent by a bridge. It was an illustrious city, the capital of Acarnania, and the place of general assembly.

LEUCATA, or *LEVATE*, (anc. geog.); a promontory of Leucadia according to Strabo, a white rock projecting into the sea towards Cephalonia, on which stood a temple of Apollo surnamed *Leucadius*. At his festival, which was annually celebrated here, the people were accustomed to offer an expiatory sacrifice to the god, and to avert on the head of the victim all the calamities with which they might be threatened. For this purpose, they made choice of a criminal condemned to die; and leading him to the brink of the promontory, precipitated him into the sea amidst the loud shouts of the spectators. The criminal, however, seldom perished in the water: for it was the custom to cover him with feathers, and to fasten birds to his body, which by spreading their wings might serve to break his fall. No sooner did he touch the sea, than a number of boats stationed for the purpose flew to his assistance, and drew him out; and after being thus saved, he was banished for ever from the territory of Leucadia. (Strabo, lib. 10. p. 452.)

According to ancient authors, a strange opinion concerning this promontory prevailed for some time among the Greeks. They imagined that the leap of Leucata was a potent remedy against the violence of love. Hence disappointed or despairing lovers, it is said, were often known to have come to Leucadia; and, having ascended the promontory, offered sacrifices

fices in the temple, and engaged by a formal vow to perform the desperate act, to have voluntarily precipitated themselves into sea. Some are reported to have recovered from the effects of the fall; and among others mention is made of a citizen of Bathroton, in Epirus, whose passions always taking fire at new objects, he four times had recourse to the same remedy, and always with the same success. As those who made the trial, however, seldom took any precaution to render their falls rapid, they were generally destroyed; and women often fell victims to this act of desperation.—At Leucata was shown the tomb of Artemisia, that celebrated queen of Caria who gave so many proofs of courage at the battle of Salamis†. Inflamed with a violent passion for a young man who inflexibly refused her love, she surprised him in his sleep and put out his eyes. Regret and despair soon brought her to Leucata, where she perished in the waves notwithstanding every effort to save her‡. Such likewise was the end of the unhappy Sappho. Forsaken by her lover Phaon, she came hither to seek relief from her sufferings, and found her death. (*Menand. ap. Sirab. lib. 10. p. 452.*)

LEUCIPPUS, a celebrated Greek philosopher and mathematician; first author of the famous system of atoms and vacuums, and of the hypothesis of storms; since attributed to the moderns. He flourished about 428 B. C.

LEUCOGÆUS, (anc. geog.), a hill situated between Puteoli and Neapolis in Campania, abounding in sulphur; now *L'Alumera*. Whence there were also springs called *Leucogæi fontes*; the waters of which, according to Pliny, gave a firmness to the teeth, cleared to the eyes, and proved a cure in wounds.

LEUCOJUM, GREAT SNOW-DROP: a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the ninth order, *Spathaceæ*. The corolla is campanulate, sexpartite, the segments increased at the points, the stigma simple.

Species. 1. The vernal, or spring leucojum, has an oblong bulbous root, sending up several flat leaves six or eight inches long; and amidst them an upright, channelled, hollow, naked stalk, about a foot high, terminated by a spatula, protruding one or two white flowers on slender footstalks drooping downwards, and appearing in March. 2. The ætival, or summer leucojum, has a large, oblong, bulbous root, crowned with several long, flat, broad leaves; and amidst them an upright, thick, hollow stalk, 15 or 18 inches high; terminated by a spatula, protruding many white flowers, on slender footstalks, drooping downwards; flowering in May. 3. The autumnale, or autumnal leucojum, hath a large oblong bulbous root, crowned with many narrow leaves, an upright, naked, hollow stalk, terminated by a spatula protruding many white flowers on long weak footstalks, hanging downwards, and flowering in autumn.

Culture. All the three species are very hardy, durable in root, and increase exceedingly by offsets, which may be separated every two or three years.

LEUCOMA, in antiquity, was a public register amongst the Athenians, in which were inserted the names of all the citizens, as soon as they were of age to enter upon their paternal inheritance.

LEUCOMA, in surgery, a distemper of the eye, otherwise called *albugo*. See *ALBUGO*, and *SURGERY*.

LEUCOPETRA, (anc. geog.) so called from its white colour (Strabo); a promontory of the Bruttii, in the territory of Rhegium: the termination of the Apennine. The utmost extremity of the Bruttii, or the modern *Calabria Ultra*; as the Japygium is of the ancient Calabria, or the modern Calabria Citra.

LEUCOPETRIANS, in ecclesiastical history, the name of a fanatical sect which sprang up in the Greek and Eastern churches towards the close of the 12th century: the fanatics of this denomination professed to believe in a double Trinity, rejected wedlock, abstained from flesh, treated with the utmost contempt the sacraments of Baptism and the Lord's Supper, and all the various branches of external worship; placed the essence of religion in internal prayer alone, and maintained, as it is said, that an evil being, or genius, dwelt in the breast of every mortal, and could be expelled from thence by no other method than by perpetual supplication to the Supreme Being. The founder of this enthusiastic sect is said to have been a person called *Leucopetrus*, and his chief disciple Ty-chicus, who corrupted, by fanatical interpretations, several books of scripture, and particularly St Matthew's gospel.

LEUCOPHLEGMATIA, in medicine, a kind of dropsy, otherwise called *anasarca*. See (*Index* subjoined to) *MEDICINE*.

LEUCOTHOE, or LEUCOTHEA (fab. hist.), the wife of Athamus, changed into a sea deity; see *ISO*. She was called *Matuta* by the Romans. She had a temple at Rome, where all the people, particularly women, offered vows for their brother's children. They did not treat the deity to protect their own children, because Ivo had been unfortunate in hers. No female slaves were permitted to enter the temple; or if their curiosity tempted them to transgress this rule, they were beaten with the greatest severity. To this supplicating for other people's children, Ovid alludes in these lines;

*Non tamen hanc pro stirpe sua pia mater adorat,
Ipsa parum felix vixisse parens.* Fast. 6.

LEUCTRA, (anc. geog.), a town of Bœotia, to the west of Thebes, or lying between Platææ and Thebæ, where the Lacedæmonians had a great defeat given them by Epaminondas and Pelopidas the Theban generals. The Theban army consisted at most but of 6000 men, whereas that of the enemy was at least thrice that number: but Epaminondas trusted most in his horse, wherein he had much the advantage, both in their quality and good management; the rest he endeavoured to supply by the disposition of his men, and the vigour of the attack. He even refused to suffer any to serve under him in the engagement, but such as he knew to be fully resolved to conquer or die. He put himself at the head of the left wing, opposite to Cleombrotus king of Sparta, and placed the main fleets of the battle there; rightly concluding, that if he could break the body of the Spartans, which was but 12 men deep, whereas his own was 50, the rest would be soon put to flight. He closed his own with the sacred band, which was commanded by Pelopidas; and placed his horse in the front. His right, from which he had drawn so many men, he ordered to fall back.

Level.
Level.

back, in a slanting line, as if they declined to fight, that they might not be too much exposed to the enemy, and might serve him for a corps of reserve in case of need. This was the wife disposition which the two Theban generals made of their few but resolute forces; and which succeeded in every part, according to their wish. Epaminondas advanced with his left wing, extending it obliquely, in order to draw the enemy's right from the main body; and Pelopidas charged them with such desperate speed and fury, at the head of his battalion, before they could reunite, that their horse, not being able to stand the shock, were forced back upon their infantry, which threw the whole into the greatest confusion: so that though the Spartans were of all the Greeks the most expert in recovering from any surprise, yet their skill on this occasion either failed them or proved of no effect; for the Thebans, observing the dreadful impression they had made on them with their horse, pushed furiously upon the Spartan king, and opened their way to him with a great slaughter.

Upon the death of Cleombrotus, and several officers of note, the Spartans, according to custom, renewed the fight with double vigour and fury, not so much to revenge his death as to recover his body, which was such an established point of honour as they could not give up without the greatest disgrace. But here the Theban general wisely chose rather to gratify them in that point, than to hazard the success of a second onset; and left them in possession of their king, whilst he marched straight against their other wing, commanded by Archidamus, and consisted chiefly of such auxiliaries and allies as had not heartily engaged in the Spartan interest: these were so discouraged by the death of the king and the defeat of that wing, that they betook themselves to flight, and were presently after followed by the rest of the army. The Thebans, however, pursued them so closely, that they made a second dreadful slaughter among them; which completed Epaminondas's victory, who remained master of the field, and erected a trophy in memory of it. This was the conclusion of the famed battle of Leuctra, in which the Lacedemonians lost 4000 men, and the Thebans but 300.

LEVEL, an instrument wherewith to draw a line parallel to the horizon, by means of which the true level, or the difference of ascent or descent between several places, may be found, for conveying water, draining fens, &c.

There are several instruments of different contrivance and matter, intended for the perfection of levelling; all of which, for the practice, may be reduced to the following.

Air-Level, that which shows the line of level by means of a bubble of air inclosed with some liquor in a glass-tube of an indeterminate length and thickness, whose two ends are hermetically sealed. When the bubble fixes itself at a certain mark, made exactly in the middle of the tube, the plane or ruler wherein it is fixed is level. When it is not level, the bubble will rise to one end. This glass-tube may be set in another of brass, having an aperture in the middle, whence the bubble of air may be observed. The liquor wherewith the tube is filled is oil of tartar, or aqua secunda; these not rarefaction and condensation, as spirit of wine is.

This application of a bubble of air was the invention of Dr Hooke.

There is one of these instruments made with sights, being an improvement upon that last described, which, by the addition of more apparatus, becomes more commodious and exact. It consists of an air-level, fig. 1. about eight inches long, and seven or eight lines in diameter, set in a brass tube, 2, with an aperture in the middle, C. The tubes are carried in a strong straight ruler, a foot long; at whose ends are fixed two sights, 3, 3, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass crossing each other at right angles, in the middle whereof is drilled a very little hole, through which a point on a level with the instrument is descried. The brass tube is fastened on the ruler by means of two screws; one whereof, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards a level. The top of the ball and socket is rivetted to a little ruler that springs, one end whereof is fastened with screws to the great ruler, and at the other end has a screw, 5, serving to raise and depress the instrument when nearly level.

The instrument just described, however, is yet less commodious than the following one; because though the holes be ever so small, yet they will still take in too great a space to determine the point of level precisely.

The instrument alluded to consists of an air-level, with telescope sights. This level (fig. 2.) is like the last; with this difference, that, instead of plain sights, it carries a telescope to determine exactly a point of level at a good distance. The telescope is a little brass-tube, about 15 inches long, fastened on the same ruler as the level. At the end of the tube of the telescope, marked 1, enters the little tube 1, carrying the eye-glasses and an hair horizontally placed in the focus of the object-glass, 2; which little tube may be drawn out, or pushed into the great one, for adjusting the telescope to different sights: at the other end of the telescope is placed the object-glass. The screw 3, is for raising or lowering the little fork, for carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4, is for making the bubble of air, D or E, agree with the telescope: the whole is fitted to a ball and socket. M. Huygens is said to be the first inventor of this level; which has this advantage, that it may be inverted by turning the ruler and telescope half round; and if then the hair cut the same point that it did before, the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying it upon, or parallel to, the base or ruler, when there is occasion to take the level of remote objects.

Dr Defaguliers contrived an instrument, by which the difference of level of two places, which could not be taken in less than four or five days with the best telescope-levels, may be taken in as few hours. The instrument is as follows. To the ball C (fig. 3.) is joined a recurve tube B A, with a very fine bore, and a small bubble at top A, whose upper part is open. It is evident from the make of this instrument, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and tube when the instrument is set upright. If the air at C be so expanded with heat, as to drive the

Level

Plate
CCLXX.

liquor

liquor to the top of the tube, the cavity A will receive the liquor, which will come down again and settle at D, or near it, according to the level of the place where the instrument is, as soon as the air at C returns to the same temperance as to heat and cold. To preserve the same degree of heat, when the different observations are made, the machine is fixed in a tin vessel EF, filled with water up to *g h*, above the ball, and a very sensible thermometer has also its ball under water, that one may observe the liquor at D, in each experiment, when the thermometer stands at the same height as before. The water is poured out when the instrument is carried; which one may do conveniently by means of the wooden frame, which is set upright by the three screws, S, S, S, fig. 4. and a line and plummet P P, fig. 5. At the back part of the wooden frame, from the piece at top K, hangs the plummet P, over a brass point at N; M m are brackets to make the upright board K N continue at right angles with the horizontal one at N. Fig. 6. represents a front view of the machine, supposing the fore part of the tin-vessel transparent; and here the brass-socket of the recurve-tube, into which the ball is screwed, has two wings at I I, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge when the water is poured in as high as *g h*.

After the Doctor had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball at A (fig. 3.) in carrying the instrument from one place to another, some of it would adhere to the sides or the ball A, and upon its descent in making the experiment, so much might be left behind, that the liquor would not be high enough at D to show the difference of the level: therefore, to prevent that inconvenience, he contrived a blank screw, to shut up the hole at A, as soon as one experiment is made, that, in carrying the machine, the air in A may balance that in C, so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument, in going from one place to another. Now, because one experiment may be made in the morning, the water may be so cold, that when a second experiment is made at noon the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time, before it comes to be as cold as it is likely to be at the warmest part of that day, observe and set down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at D; then screw on the cap at A, pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometer is come to the same degree as before, open the screw at top, and observe the liquor in the barometer.

The Doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each tenth of an inch answering to a foot in height.

The Doctor made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains (though, with a proper allowance for the decreasing density of the air, it will do very well), but for heights that want to be known

in gardens, plantations, and the conveyance of water, where an experiment that answers two or three feet in a distance of 20 miles, will render this a very useful instrument.

Artillery Foot-Level is in form of a square, having its two legs or branches of an equal length; at a juncture whereof is a little hole, whence hangs a thread and plummet playing on a perpendicular line in the middle of a quadrant. It is divided into twice 45 degrees from the middle. Fig. 7.

This instrument may be used on other occasions, by placing the ends of its two branches on a plane; for when the thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level. To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height, by means of the plummet, whose thread will give the degree above the level.

Carpenter's and Pavior's Level, consists of a long ruler, in the middle whereof is fitted, at right angles, another somewhat bigger, at the top of which is fastened a line, which, when it hangs over a fiducial line at right angles with the base, shows that the said base is horizontal. Sometimes this level is all of one board. Fig. 8.

Gunner's Level, for levelling cannons and mortars, consists of a triangular brass plate, about four inches high, fig. 9. at the bottom of which is a portion of a circle, divided into 45 degrees; which number is sufficient for the highest elevation of cannons and mortars, and for giving shot the greatest range: on the centre of this segment of a circle is screwed a piece of brass, by means of which it may be fixed or screwed at pleasure: the end of this piece of brass is made so as to serve for a plummet and index, in order to show the different degrees of elevation of pieces of artillery. This instrument has also a brass foot, to set upon cannons or mortars, so as, when those pieces are horizontal, the instrument will be perpendicular. The foot of this instrument is to be placed on the piece to be elevated, in such a manner, as that the point of the plummet may fall on the proper degree: this is what they call *levelling the piece*.

Mason's Level, is composed of three rules, so joined as to form an isosceles-rectangle, somewhat like a Roman A; at the vertex whereof is fastened a thread, from which hangs a plummet, that passes over a fiducial line, marked in the middle of the base, when the thing to which the level is applied is horizontal; but declines from the mark, when the thing is lower on the one side than on the other.

Plumb or Pendulum Level, that which shows the horizontal lines by means of another line perpendicular to that described by a plummet or pendulum. This instrument, fig. 10. consists of two legs or branches, joined together at right angles, whereof that which carries the thread and plummet is about a foot and a half long; the thread is hung towards the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, so that it may hang free every where: but towards the bottom, where there is a little blade of silver, whereon is drawn a line perpendicular to the telescope, the said cavity is covered by two pieces of brass, making as it were a kind of case, lest the wind should agitate the thread; for which reason the silver blade is covered with a glass G, to the

Level.

end that it may be seen when the thread and plummet lay upon the perpendicular: the telescope is fastened to the other branch of the instrument, and is about two feet long; having an hair placed horizontally across the focus of the object-glass, which determines the point of the level. The telescope must be fitted at right angles to the perpendicular. It has a ball and socket, by which it is fastened to the foot, and was invented by M. Picard.

Reflecting Level, that made by means of a pretty long surface of water representing the same object inverted which we see erected by the eye, so that the point where these two objects appear to meet is a level with the place where the surface of the water is found. This is the invention of M. Marriotte.

There is another reflecting level consisting of a mirror of steel, or the like, well polished, and placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must make an angle of 45° with the telescope, in which case the perpendicular line of the said telescope is converted into a horizontal line, which is the same with the line of level. This is the invention of M. Cassini.

Water-Level, that which shows the horizontal line by means of a surface of water or other liquor; founded on this principle, that water always places itself level.

The most simple is made of a long wooden trough or canal, whose sides are parallel to the base; so that being equally filled with water, its surface shows the line of level. This is the chorobates of the ancients. See CHOROBATA.

It is also made with two cups fitted to the two ends of a pipe, three or four feet long, about an inch in diameter, by means whereof the water communicates from the one to the other cup; and this pipe being moveable on its stand by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extreme of the pipe with wax or mastic. Into the pipe is poured some common or coloured water, which shows itself through the cylinders, by means whereof the line of level is determined; the height of the water, with respect to the centre of the earth, being always the same in both cylinders; this level, though very simple, is yet very commodious for levelling small distances.

Level of Mr Huygens's invention, consists of a telescope *a*, fig. 11. in form of a cylinder, going through a ferril, in which it is fastened by the middle. This ferril has two flat branches *bb*, one above, and the other below: at the ends whereof are fastened little moving pieces, which carry two rings, by one of which the telescope is suspended to an hook at the end of the screw 3, and by the other a pretty heavy weight is suspended, in order to keep the telescope in *equilibrium*. This weight hangs in the box 5, which is almost filled with linseed oil, oil of walnuts, or other matter that will not easily coagulate, for more aptly settling the balance of the weight and telescope. The instrument carries two telescopes close and very parallel to each other; the eye-glass of the one being against the object-glass of the other, that one may see each way

Level.

without turning the level. In the focus of the object-glass of each telescope must a little hair be strained horizontally, to be raised and lowered as occasion requires by a little screw. If the tube of the telescope be not found level when suspended, a ferril or ring, 4, is put on it, and is to be slid along till it fixes to a level. The hook on which the instrument is hung is fixed to a flat wooden cross; at the ends of each arm whereof there is a hook serving to keep the telescope from too much agitation in using or carriage. To the said flat cross is applied another hollow one, that serves as a case for the instrument; but the two ends are left open, that the telescope may be secured from the weather and always in a condition to be used. The foot of this instrument is a round brass plate, to which are fastened three brass ferrils, moveable by means of joints whereon are put slaves, and on this foot is placed the box.

Fig. 12. marked I, is a balance-level; which being suspended by the ring, the two lights, when in *equilibrium*, will be horizontal, or in a level.

Spirit Level. The most accurate levelling instrument, and that possessed of the greatest essential advantages in use, is the spirit-level; which was first constructed by the late Mr Sisson, and to which some small additions and improvements have been since made. The following is a description of one of the best of these levels, as made by the principal mathematical instrument makers.

Fig. 13. is a representation of the instrument mounted on its complete slaves, copied (except the letters) from Mr Adams's Graphical Essays, Plate xvii. fig. 3. The telescope (ABC) is made from 15 inches to 2 feet in length, as may be required. It is achromatic, of the best kind, and shows the objects erect. In the focus of the eye-glasses are exceedingly fine cross wires, the intersection of which is evidently shewn to be perfectly in the axis of the tube; for by turning it round on its two supporters DE, and looking through the telescope, the intersection of the wires will constantly cut the same part of the object viewed. By turning the screw *a* at the side of the telescope, the object-glass at *g* is moved; and thus the telescope is exactly adapted to the eye. If these cross wires are at any time out of their adjustment, which is discovered by their intersection not cutting the same part of the object during the revolution of the telescope on its axis, they are easily adjusted by means of the four screws *bbb*, placed on the telescope about an inch from the end for the eye. These screws act in perpendicular directions to one another, by unscrewing one and tightening the other opposite to the wire, so that if connected with it, it may be moved either way at pleasure; and in this manner the other wire perpendicular to it may be moved, and thus the intersection of the wires brought exactly in the axis of the tube.

To the telescope is fixed, by two small screws *cc*, the level tube containing the spirits, with a small bubble of air: This bubble of air, when the instrument is well adjusted, will settle exactly in the same place, in or near the middle of its tube, whether the telescope be reversed or not on the supporters, which in this case are kept unmoved.

It is evident, that the axis of the telescope, or the intersection of the wires, as before shown, must be in this case

Level cafe truly level. In this facile mode of adjustment confists the new improvement of the instrument; and it is hereby capable of being adjusted by only one station and one object, which will at the same time determine it to be in a true level. If by change of weather, accident, or otherwise, the instrument should have lost its level adjustment or state, it may thus be readily restored and readjusted at the first station; which is an advantage none of the instruments formerly made have been capable of. The two supporters DE, on which the level rests and turns, are shaped like the letter Y. The telescope rests within the upper part of them; and the inner flides of each of these Ys are tangents to the cylindric tube of the telescope, which is turned to a true cylinder, and each touches it but at one place only.

The lower end of these supporters are inserted into a strong brass plate (FE), and so as to stand perpendicularly on it. One is kept fast by a tightening screw G, and to the other is applied a fine threaded screw H, to adjust the tube when on its supporters to a true level. To the supporter D is sometimes applied a line of tangents as far as 12 degrees, in order to take an angle of depression or elevation to that extent. Between the supporters is also sometimes fixed a compass-box I, divided into 360 degrees, and again into four 90°; having a centre pin and needle, and trigger, at *d*, to throw off the needle from the centre when not used; so in this manner it constitutes a perfect circumference, connected with all the foregoing improvements. This plate is fixed on a conical brass ferrel K, which is adapted to the bell-metal frustum of a cone at top of the brass head of the flaves, having a ball and socket, with three bell-metal joints, two strong brass parallel plates LL, the four screws *eeee* for adjusting the horizontal motion, a regulating screw M to this motion, and a fastening screw N to lighten it off the cone when necessary. The fastening screw N, and the regulating screw M, by which the whole instrument is moved with accuracy through a small space in an horizontal direction, was an addition of Mr Ramsden's.

The manner of adjusting the spirit-level at the first station. The whole level being now placed steadily on its flaves, it must be rendered parallel to the axis of the telescope before you adjust the horizontal motion. To this end the telescope must be placed in a line with two of the screws *ee*, and then levelled thereby till the bubble of air in the spirit-tube keeps its position in the middle, while turned about to three points, making nearly right angles at the centre to one another.

The horizontal motion being thus adjusted, the rims *ff* of the Ys are to be opened, the telescope taken off and laid the contrary way upon the supporters. If the bubble of air then rests exactly the same, the level and telescope are adjusted rightly to one another; but if the bubble does not remain the same, the end to which the air bubble goes must be noticed, and the distance of it from the telescope altered; correcting one half the error by the screws *ee*, and the other half by the screws *ee*.

Now the intersection of the wires being directed to any distant object, it may be one of the vanes of the flaves hereafter described; if they continue to be

Levelling, against it precisely while the telescope is turned round on its Ys, it proves, as before mentioned, that the axis of the telescope coincides with the intersection of the wires, and that the instrument will give the true level direction.

The operation of levelling being of a very accurate and important nature, and the best instrument when out of its adjustment being of little use, it is quite necessary that every person using such an instrument should have it readily in his power to correct it; and the one above described appears to be the best adapted for that purpose of any hitherto contrived.

LEVELLING may be defined, the art which instructs us in finding how much higher or lower any given point on the surface of the earth is than another; or, in other words, the difference in their distance from the centre of the earth.

The practice of levelling therefore consists, 1. In finding and marking two or more points that shall be in the circumference of a circle whose centre is that of the earth. 2. In comparing the points thus found with other points, to ascertain the difference in their distances from the earth's centre.

With regard to the theory of levelling, we must observe, that a plumb-line, hanging freely in the air, points directly towards the centre of the earth; and a line drawn at right angles, crossing the direction of the plumb-line, and touching the earth's surface, is a true level only in that particular spot; but if this line which crosses the plumb be continued for any considerable length, it will rise above the earth's surface, and the apparent level will be above the true one, because the earth is globular; and this rising will be as the square of the distance to which the said right line is produced; that is to say, however much it is raised above the earth's surface at one mile's distance, it will rise four times as much at the distance of two miles, nine times at the distance of three, &c. This is owing to the globular figure of the earth; and this rising is the difference betwixt the true and apparent levels; the real curve of the earth being the true level, and the tangent to it the apparent level. Hence it appears, that the less distance we take betwixt any two stations, the truer will be our operations in levelling; and so soon does the difference betwixt the true and apparent levels become perceptible, that it is necessary to make an allowance for it if the distance betwixt the two stations exceeds two chains in length. The following is an infallible rule for determining the allowance to be made:

"Multiply the number of Gunter's decimal statute *Lead's* ^{*and* *navigational*} chains that are contained in length between any two stations where the levels are to be taken by itself, and the product arising therefrom again by 124; which is a common multiplier for all manner of distances for this purpose on account of the earth's curvature: then divide the second product arising therefrom by 100,000; or, which is also the same, with the dath of the pen cut off five figures on the right hand side of the product, and what remains on the left side is inches, and the five figures cut off decimal parts of an inch."

Levelling. The following is *A Table of Curvature of the Earth* and shows the quantity below the apparent level at the end of every number of chains to 100.

Chains.	Inches.	Chains.	Inches.	Chains.	Inches.	Chains.	Inches.
10.00125	14	0.24	27	0.91	40	2.00	
20.005	15	0.28	28	0.98	45	2.28

130.21	26	0.84	39	1.91	100	12.50	

Levelling is either simple or compound. The former is when the level points are determined from one station, whether the level be fixed at one of the points or between them. Compound levelling is nothing more than a repetition of many simple operations.

An example of simple levelling is given Plate CCLXXI. fig. 1. where A B are the station points of the level; C D the two points ascertained. Let the height

	Feet.	Inches.
From A to C be	6	0 0
From B to D be	9	0 0

The difference - 3 0 0 shows that B is three feet lower than A.

If the station-points of the level are above the line of sight, as in fig. 2. and the distance from A to C be six feet, and from B to D nine feet, the difference will still be three feet which B is higher than A.

As an example of compound levelling, suppose it were required to know the difference of height between the point A on the river *Zome*, and N on the river *Belann*, fig. 3. (As our author could find no satisfactory examples in any English author, he copied this and the following ones from M. le Febure). In this operation stakes should be driven down at A and N, exactly level with the surface of the water; and these stakes should be so fixed, that they may not be changed until the whole operation be finished: a plan of the ground between the two rivers should then be made, by which it will be discovered, that the shortest way between the rivers is by the dotted line AC, CH, HN; from whence also the number of stations necessary to be taken will be determined. The operator will also be enabled to distribute them properly according to the nature and situation of the ground. In the figure 12. stations are marked. Stakes ought then to be driven in at the limits of each station, as A, B, C, D, &c. They ought to be about two or three inches above the ground, and driven 18 inches into it. Stakes should also be driven in at each station of the instrument, as 1, 2, 3, 4, &c.

The operation may be begun in the following manner. Let the first station be at 1, equally distant from the two points A and B, which themselves are distant 166 yards. Write down then in one column the first limit A; in another, the number of feet, inches, and tenths; with the points of sight indicated on the station-staff at A, viz. 7. 6. 0. In the third column, the second limit B; in the fourth, the height indicated at the station-staff B, viz. 6. 0. 0. Lastly, in the fifth column, the distance from one station-staff to the other; which in this case is 166 yards. Remove now the level to the point marked 2, which is in the middle between B and C, the two places where the station-staves are to be held; observing that B, which was the second limit in the former operation, is the first in this. Then write down the observed heights as before; in the first column B; in the second 4. 6. 0; in the third C; in the fourth 5. 6. 2; in the fifth 560, the distance between B and C.

If being impossible, on account of the inequality of the ground at the third station, to place the instrument in the middle between the two station-staves, find the most convenient point as at 3; then measure exactly how far this is from each station-staff, and you will find that from 3 to C is 160 yards; from 3 to D, 80 yards; and the remainder of the operation will be as in the preceding station.

In the fourth operation, we must endeavour to compensate for any error which might have happened in the last. Mark out, therefore, 80 yards from the station-staff D to the point 4; and 160 yards from 4 to E; and this must be carefully attended to, as by such compensations the work may be much facilitated. Proceed in the same manner with the eight remaining stations, observing to enter every thing in its proper column; and when the whole is finished, add the sums of each column together, and then subtract the lesser from the greater; the difference, which in the present case is 5. 4. 8. shows the ground at N to be thus much lower than the ground at A.

To obtain a section of this level, draw the dotted line *oo*, fig. 4. either above or below the plan; which may be taken for the level or horizontal line. Let fall then perpendiculars upon this line from all the station-points and places where the station-staves were fixed. Beginning now at A, set off 7 feet 6 inches upon the line from A to *a*: for the height of the level-point determined on the staff at this place, draw a line through *a* parallel to the dotted line *oo*, which will cut the third perpendicular at *b*, the second station-staff. Set off from this point downwards six feet to B, which shows the second limit of the first operation; and that the ground at B is one foot six inches higher than at A: place your instrument between these two lines at the height of the level line, and trace the ground according to its different heights. Now set off, on the second station-staff B, four feet six inches to C, the height determined by the level at the second station; and from C draw a line parallel to *oo*, which will cut the fifth perpendicular at *d*, the third station-staff. From this point set off 5 feet 6 inches $\frac{1}{2}$ downwards to C, which will be our second limit with respect to the preceding one and the third with respect to the first. Then draw your instrument in the middle between B and C, and delineate the ground with its inequalities. Proceed

Levelling. ceed in the same manner from station to station, till you arrive at the last N, and you will have the profile of the ground over which the level was taken.

This method answers very well where only a general profile of the different stations is required; but where it is necessary to have an exact detail of the ground between the limits, we must then go to work more particularly. Suppose, therefore, the level to have been taken from A to N by another route; but on more uniform ground, in order to form a canal marked O, P, Q, R, S, T, U, X, Y. Draw at pleasure a line Z, Y, fig. 5. to represent the level, and regulate the rest; then let fall on this line perpendiculars to represent the stakes at the limits of each station, taking care that they be fixed accurately at their respective distances from each other. The difference between the extreme limits, in this case, ought to be the same as in the former, viz. 5 feet 4 inches $\frac{1}{2}$. Set off this measure upon the perpendicular *o* the first limit; and from *o*, prolonging the perpendicular, mark off at *a* the height determined at the first station-staff; then do the same with the second and third, and so on with the following, till this part of the work is finished; there remains then only to delineate in detail the ground between the station-stakes, the distances in this example being assumed larger on account of the detail.

To obtain the section of the ground between O and P, place your instrument at one of the limits, as P, fixing it so that the cross hairs may answer to the point C; then look towards the first limit *o*, raising or depressing the vane till it coincides with the intersection of the cross hairs; and the line of sight from one point to the other will mark the level or horizontal line.

To set off the height of the brink of the river above the first limit, drive a stake down close to the ground at *a*; and place your station-staff upon it, observing where the hairs intersect the vane, which will be at 4 feet 10 inches; then, laying off upon the line *oz* the distance from the first to the last stake, let fall from thence a perpendicular, and set off thereon 4. 10. 0 to *a*, which gives the height at the first stake; or, which is the same, the height from the edge of the river above the surface of the water, as is evident from the section. Draw a second stake at *b*, in a line between the limits; place the station-staff upon this stake, and observe the height 4. 6. intersected by the cross hairs, the instrument still remaining in the same situation. Set off on the level-line the distance from the first stake *a* to the second *b*; and then let fall a perpendicular, and mark upon it 4. 6 to *b*, which gives the height of the ground at this place.

The small hollow *c* is marked out by driving down a third stake even with the ground, in the middle of it at *c*; but the exact distance of the second stake *b* from the third *c*, must be marked upon the level line: then let fall a perpendicular from *c*, and set off upon it 6. 8. 0, pointed out by the cross hairs on the staff, which determines the depth of the hollow, as appears from the figure. As the distances between the stakes are now very short, they can easily be marked by the operator, who can settle any little inequalities by a comparison with those already ascertained. Proceed thus with the other stations till you arrive at the last, and you will always obtain an accurate section of your

work; by which it is easy to form a just estimation of the land to be dug away, in order to form the canal, by adding the depth to be given to it.

Fig. 6. gives an example of compound levelling, where the situation is so steep and mountainous, that the stakes cannot be placed at equal distances from the instrument, or where it is even impossible to make a reciprocal levelling from one station to the other. Thus suppose the point K to be the bottom of a bafon where it is required to make a fountain, the reservoir being at *A*; so that, in order to know the height to which the jet d'eau will rise, it is necessary to know how high the point A is above K.

In great heights such as this, it will be necessary to proceed by small descents, as from A to D. The instrument must be adjusted with all possible care; and it will even be proper, in some part of the work, to use a smaller instrument. The following is a table of the different operations used in making this level, it having been taken from M. le Febure's practice.

	feet	in.	feet	in.	yards
A	21	6	C	0	9 90
C	4	3	D	0	3 40
D	3	9	E	16	3 350
E	5	0	F	17	9 250
F	10	6	G	5	0 375
G	5	0	H	19	0 300
H	5	0	K	47	3 1000
	95	0		106	9 2405

In this case only two levellings are made between A and D, though more would have been necessary; but they are omitted to avoid confusion. In the fourth station the height found was 16 feet 8 inches; but on account of the great length, it was requisite to reduce the apparent level to the true one, which is always necessary where the length is considerable. At the last limit we get the height from N to *o*; then from *o* to I; from I to K, fig. 7. &c.; all which added together, and then corrected for the curvature, gives 47 feet 3 inches. Now, by adding each column together, and subtracting one from the other, we have 51 feet 9 inches for the height which the point A is above the bottom of the bafon, and which will cause the jet d'eau to rise about 45 feet. The general section of this operation is shown at fig. 7. 8. but an exact profile of the mountain is more difficult, as requiring many operations; though some of these might be obtained by measuring from the level line without moving the instrument.

The last example given by our author is likewise from M. le Febure, and includes a length of near five German miles (25 of ours) in a straight line, and 9 or 10 (45 or 50 English) including the turnings and windings. In this the declivity of the river Haynois was measured from Lignebruk to Villebourg. The first operation was to drive stakes at several parts of the river even with the water's edge; the first of which a little above the mills of Lignebruk showed the upper water-mark, and another showed the lower water-mark at the same mills. Two stakes above and below the mills of Mazuranc, somewhat more than half way between Lignebruk and Villebourg, pointed

Levelling
 ||
 Lever.

out the difference between high and low water there, and formed likewise the third and fourth limits of the operation; while the stakes above and below the mills of Villebourg pointed out the difference between high and low water, and likewise formed the last limits of the operation.

These marks were all made at the edge of the water, exactly even with its surface, and all made at the different parts of the river nearly at the same instant of time. "The principal limits of the levelling (says Mr Adams) being now determined and fixed, it only remains to find the level between the limits, according to the methods already pointed out, using every advantage that may contribute to the success of the work, and at the same time avoiding all obstacles and difficulties that may retard or injure the operations. The first rule is always to take the shortest possible way from one limit to another, though this rule ought not to be followed if there are considerable obstacles in the way, as hills, woods, marshy ground, or if, by going aside, any advantage can be obtained." In the present case it was found necessary to deviate very considerably from the general rule, in order to take in several ponds, the surfaces of which might all be taken for a perfect level; and thus levels were frequently taken across the country for a considerable way. The difference of height between the mills of Lignebruk and Villebourg was at last found to be about 19 feet, indicating a descent of not quite a foot in a mile.

LEVELLING-STAVES, instruments used in levelling, serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist of two mahogany flaves ten feet long, in two parts, that slide upon one another to about $5\frac{1}{2}$ feet, for the more portable carriage. They are divided into 1000 equal parts, and numbered at every tenth division by 10, 20, 30, &c. to 1000; and on one side the feet and inches are also sometimes marked.

A vane A slides up and down upon each set of these flaves, which by brass springs will stand at any part. These vanes are about 10 inches long and 4 inches broad; the breadth is first divided into three equal parts, the two extremes painted white, the middle space divided again into three equal parts, which are less; the middle one of them is also painted white, and the two other parts black; and thus they are suited to all the common distances. These vanes have each a brass wire across a small square hole in the centre, which serve to point out the height correctly, by coinciding with the horizontal wire of the telescope of the level.

LEVEN, a river of Lenox or Dunbartonshire in Scotland. See LENOX.

LEVER, in mechanics, is a bar of iron or wood, one part of which being supported by a prop, all other parts turn upon that prop as their centre of motion. This instrument is of two kinds. First, the common sort, where the weight we desire to raise, rests at one end of it, our strength is applied at the other end, and the prop is between both. When we stir up the fire with a poker, we make use of this lever; the poker is the lever, it rests upon one of the bars of the grate as a prop, the incumbent fire is the weight to be overcome, and the other end held in the hand is the strength

or power. In this as in all the rest, we have only to increase the distance between the strength and prop to give the man that works the instrument greater power.

The lever of the second kind, has the prop at one end, the strength is applied to the other, and the weight to be raised rests between them. Thus in raising the water-plug in the streets, the workman puts his iron lever through the hole of the plug till he reaches the ground on the other side, and, making that his prop, lifts the plug with his strength at the other end of the lever. In this lever also, the greater the distance of the prop from the strength, the greater is the workman's power.

These instruments, as we see, assist the strength; but sometimes a workman is obliged to act at a disadvantage, in raising either a piece of timber or a ladder upon one end. We cannot, with grammatical propriety, call this a *lever*, since such a piece of timber in fact in no way contributes to raise the weight. In this case, the man, who is the strength or power, is in the middle, the part of the beam already raised is the weight, the part yet at the ground is the prop on which the beam turns or rests. Here the man's strength will be diminished, in proportion to the weight it sustains. The weight will be greater the farther it is from the prop, therefore the man will bear the greater weight the nearer he is to the prop. See MECHANICS.

LEVERET, among sportsmen, denotes a hare in the first year of her age.

LEVIGATION, in pharmacy and chemistry, the reducing hard and ponderous bodies to an impalpable powder, by grinding them on a porphyry, or in a mill. See CHEMISTRY, n^o 599.

A new method of reducing powders to a great degree of fineness has lately been invented by means of a fanner. This has the advantage over the other methods, in being much more expeditious, and attended with less trouble and expence; the degree of fineness to which they are reducible being thus also in a manner unlimited. The construction of the fanner employed for this purpose is different from that employed for winnowing corn; the blast not being collected into a small compass as in the latter, but diffused over a considerable space, lest a violent blast should hurry off both coarse and fine together. For this purpose, the leaves of the fanner are made as long in the direction parallel to the axis as can be done conveniently. In the other direction projecting from it, they differ not from the ordinary length, nor do they in the general situation with respect to each other. Before the leaves is a wooden partition reaching half way up, to prevent the gross powder from falling in among the leaves, which reaches about half way from bottom to top; and about two feet or less from this, according to the size of the fanner, is another partition in a sloping direction, reaching from the bottom of the box to near the top. The whole is inclosed in a large box six or seven feet long, having in the end farthest off from the leaves a slit equal to the space left betwixt the top of the box and the sloping partition already mentioned. On the top of this is another box, extending from the farthest end of the former to the hopper which holds the coarse powder, with a hole in the end nearest to the fanner; and upon this another

Leveret,
 Levigation.

 fig. 14.

Levigation. box, &c. as long as it is found that the air carries off with it any quantity of powder. This will be best understood from the following description of the figure.

Plate CCLXXXI. A represents the fanter itself, having a hole in the case for the admission of the air, as usual.

B, The first wooden division, to prevent the return of the powder upon the leaves of the fanter.

C, The second division, reaching not quite to the top of the box. Its use is to direct the current of air produced by the fanter obliquely upwards: thus it strikes the powder, falling down from the hopper, in the same oblique direction, and carries off the fine parts, first through the aperture *a*; after which some of them are lodged in the box D; the still finer particles are carried through the aperture *b* into the second box E, where part of them are lodged: they next pass through the aperture *c* into the box F, and through *d* into the box G; the powder becoming still finer and in smaller quantity as it ascends into the higher boxes, until at last the waste becomes so trifling, that the air may be allowed to pass off entirely through the aperture *b* in the fourth or some other box, as is found most convenient.

Thus it is evident we may obtain powders of every degree of fineness, and such as neither sieve nor levigating mill could equal. Washing over with water may indeed produce powders equally fine; but the length of time requisite for settling, and the trouble of drying them again, must decidedly give the preference to the fanter; especially when we consider, that there is not any occasion for taking out the powder in small quantities, as is the case in sifting, washing, or levigating; but it may be allowed to remain till as much is collected in the boxes as we desire.

The principal difficulty in the construction of this fanter is the letting down the powder in a proper manner, so that the stream of air, which ought not to be very strong, may freely pass through it. For this purpose, the hopper must not let it fall in a large body, as in winnowing of corn, but in a long and thin sheet, which can easily be pervaded. The best method seems to be to make the hopper extend the whole breadth of the box, having a narrow slit at bottom. Close on the under part of this slit, a fluted roller ought to turn, which shutting up the aperture exactly, cannot allow any powder to pass but what does so in consequence of the hollow flutes of the roller; for a smooth round one would allow nothing to pass. It would be proper also that the flutes be but small, that a thin and nearly continued stream of powder be always descending; for this will contribute greatly to the fineness of the produce: and on this account the powder ought, before it is put into the hopper, to be passed through a lawn sieve. In the figure, *e* represents the hopper, and *f* the fluted roller. Motion is easily communicated to the latter by means of a wheel fastened on the axis of the fanter.

The coarse powder is kept back by the partition C, and descends through a slit *i* in the bottom of the lowermost box, into a receptacle *k*, which may be removed occasionally. All the joints and seams of the machine must be very close, for the fine powder is very penetrating; for this reason also the hopper ought to have a lid.

LEWDNESS. See FORNICATION.—Lewdness is punishable by our law by fine, imprisonment, &c. And Mich. 15 Car. II. a person was indicted for open lewdness, in showing his naked body in a balcony, and other misdemeanors; and was fined 2000 marks, imprisoned for a week, and bound to his good behaviour for three years. 1 Sid. 168. In times past, when any man granted a lease of his house, it was usual to insert an express covenant, that the tenant should not entertain any lewd women, &c.

LEVITE. In a general sense, means all the descendants of Levi, among whom were the Jewish priests themselves, who, being descended from Aaron, were likewise of the race of Levi. In a more particular sense, *Levite* is used for an order of officers in that church, who were employed in performing the manual service of the temple. They were obedient to the priests in their ministrations, and brought them wood, water, and other necessities for the sacrifice.—They sung and played upon instruments in the temple and in other places. They applied themselves to the study of the law, and were the ordinary judges of the country, but always subordinate to the priests. Their subsistence was the tithes of corn, fruit, and cattle, throughout Israel: but the priests were intitled to a tenth of their tithes, by way of first-fruits to the Lord. Eight and forty cities were assigned for the residence of the Levites, of which the priests claimed thirteen, six whereof were chosen for cities of refuge. They were consecrated, before they entered upon their ministry, by shaving their flesh, washing their cloaths, and sprinkling with the water of expiation. Imposition of hands was used in consecration, and two bullocks were offered at the door of the tabernacle. They waited weekly, and by turns, in the temple, beginning their attendance on one sabbath and ending the next: During this time they were maintained out of the offerings, &c. In the time of Solomon, the number of Levites, from the age of 20 and capable of serving, was 38,000.

LEVITICUS, a canonical book of the Old Testament, so called from its containing the laws and regulations relating to the priests, Levites, and sacrifices.

LEVITY, in physiology, the privation or want of weight in any body when compared with another that is heavier than it; in which sense it stands opposed to gravity.

LEUK, a town of Switzerland, almost in the middle of the Valais; remarkable for its natural strength, for the assembly of the states that often meet there, and for its baths, whose water is so hot that they will boil eggs.

LEUNCLAVIUS (Joannes), a learned German, was descended from a noble family, and born at Amelbrun in Westphalia, 1533. He travelled through almost all the countries in Europe. While he was in Turkey, he collected very good materials for an "History of the Ottoman Empire;" which he published, and also several other pieces concerning it, in Latin. He gave Latin translations also of Xenophon, Zosimus, &c. To a knowledge of the learned languages he added that of the civil law. He died at Vienna in 1593, aged 60.

LEUSDEN (John), a celebrated philologist, born in

Levite
||
Leusden.

Leutkirk in 1624. He studied the learned languages and mathematics at Utrecht; and then went to Amsterdam, to converse with the rabbis, and perfect himself in the Hebrew tongue. After which he was professor of Hebrew at Utrecht, where he acquired a great reputation, and died in 1699. He wrote many valuable works; the principal of which are, 1. *Onomasticum Sacrum*, 8vo. 2. *Clavis Hebraica & Philologica Veteris Testamenti*, 4to. 3. *Novi Testamenti Clavis Græca, cum Annotationibus Philologicis*, 8vo. 4. *Compendium Bibliæ Veteris Testamenti*, 8vo. 5. *Compendium Græcæ Novi Testamenti*; the best edition of which is that of London, in 1668, 12mo. 6. *Philologus Hebraeus*, 4to. 7. *Philologus Hebraeus mixtus*, 4to. 8. *Philologus Hebraeus Græcus*, 4to. 9. Notes on Jonas, Joel, Hosea, &c. He also gave correct editions of several learned works.

LEUTKIRK, a free and imperial town of Germany, in Suabia, and in Algow, seated on a rivulet that falls into the Illar, in E. Long 10. 10. N. Lat. 47. 53.

LEUTMERITZ, a town of Bohemia, capital of a circle of the same name, with a bishop's see, seated on the river Elbe, in E. Long. 14. 25. N. Lat. 50. 34.

LEWARDEN, a handsome, rich, and strong town of the United Provinces, capital of Oostergow, Westergow, Sevenwolden, and West Friesland. It was the usual place of residence of the Stadtholder; and in buildings, as well public as private, is very magnificent. It has several canals running through the streets, which are of great service to their trade, especially as they are continued to the sea and to the most considerable towns of the province. E. Long. 5. 42. N. Lat. 53. 12.

LEEUEWENHOEK (Anthony de), a celebrated Dutch physician and naturalist, was born at Delft in 1632, of an ancient family of that city; and acquired a very great reputation throughout all Europe, by his experiments and discoveries. He particularly excelled in making glasses for microscopes and spectacles, and died in 1723. His letters to the royal society of London, of which he was a member, were printed at Leyden, in 1722, in 4to.

LEVY, in law, signifies to gather or collect; as to levy money, and to levy a fine of lands in the passing a fine.

LEWENTZ, a town of Upper Hungary, in the county of Gran, and on the river of the same name, where the Turks were defeated in 1644. E. Long. 18. 19. N. Lat. 48. 15.

LEWES, a large well-built town of Sussex in England, seated on an eminence on the banks of the river Ouse, 50 miles from London. It is famous for a bloody battle near it, wherein King Henry III. was defeated and taken prisoner by the barons; and is so ancient, that we read the Saxon king Athelstan appointed two mint-houses here, and that in the reign of Edward the Confessor it had 127 burgesses. It is a borough by prescription, by the style of constables and inhabitants. The constables are chosen yearly. It has handsome streets and two suburbs, with six parish churches. It carries on a good trade; and the river Ouse runs through it, which brings goods in boats and barges from a port 8 miles off. On this river are several iron-works, where cannon are cast for merchant-ships, besides other useful works. A charity-

school was opened here in 1711, where 20 boys are taught, clothed, and maintained, at the expence of a private gentleman, by whom they were also furnished with books; and 8 boys more are taught here at the expence of other gentlemen. Here are horse-races almost every summer for the king's plate of L. 100. The roads here are deep and dirty; but then it is the richest soil in this part of England. The market here is on Saturday; and the fairs May 6. Whitfun-Tuesday, and October 2. The timber of this part of the county is prodigiously large. The trees are sometimes drawn to Maidstone and other places on the Medway, on a sort of carriage called a *rag*, drawn by 22 oxen a little way, and then left there for other tugs to carry it on; so that a tree is sometimes two or three years drawing to Chatham; because, after the rain is once set in, it fits no more that year, and sometimes a whole summer is not dry enough to make the roads passable. It is cheap living here; and the town not being under the direction of a corporation, but governed by gentlemen, it is reckoned an excellent retreat for half-pay officers, who cannot so well confine themselves to the rules of a corporation. It lends two members to parliament.

LEWIS, one of the largest of the Hebrides or western islands of Scotland, extending about 60 miles in length from north to south, and from 13 to 14 in breadth, consisting of a great number of isles and rocks, and parted by the sea into two divisions, called *Lewis* and *Harrie*, the former lying to the westward of the other. Lewis belongs to the shire of Ross; is divided by several channels, distinguished by several names, and partitioned out among different proprietors; but the *Lewis*, strictly so called, stretches about 36 miles in length, from the north point of Bowling-head to the southern extremity of Kuffiness in Harries. The air is temperately cold, moist, and healthy; great part of the low ground is flooded with lakes; the rest is arable in many places, and has been counted fruitful in oats, barley, rye, flax, and hemp. The soil in these parts is a light sand, which the inhabitants manure with foot and sea-ware; but great part of the island is covered with heath. The labouring people dig the land with spades, and break the clods with small harrows, the foremost teeth of which are made of wood, and the remainder of rough heath, which smooths what the others have broken; and this harrow is drawn by one man, having a strong trace of horse-hair across his breast. Of their corn they not only make malt for ale, but likewise a strong spirit called *trifflarg*, which is the whisky, or usquebaugh, three times distilled. Lewis abounds with convenient bays and harbours, in which are caught, in great plenty, cod, ling, and herring: here are likewise whales of different sizes, which the natives drive into the bays, and kill with harpoons. These bays afford great plenty of shell-fish, such as clams, oysters, cockles, mussels, limpets, welks, and such a prodigious quantity of spout-fish is sometimes cast up from the land off Loch-tua, that they infect the air, and render it unhealthy to the neighbouring inhabitants, who are not able to consume them, either by eating, or using them as manure for the ground. Some of these lochs and bays likewise produce small coral and coralline. The fresh-water lakes are well stored with trout and eels, and the rivers

yield

Leutkirk
||
Lewes

Lewis.

Lewis.

yield plenty of salmon. Along the coast are found a great number of caves, which serve as shelter for the seals and otters, which are also eaten as dainties by the inhabitants; and vast numbers of sea-fowl build upon the rocks and promontories.

The land-animals reared in this island, are cows, horses, sheep, goats, hogs, and deer; all these are of a diminutive size. The beef, mutton, and pork, are juicy and delicious; the horses are active and hardy: the deer, which are of the red kind, confine themselves to the chace of Ofervaul, about 15 miles in compass, which affords tolerable pasturage; but in the winter, when the ground is covered with frost and snow, these animals are forced to feed on sea-ware, and endure all the rigour of the season, without any shelter from wood or copse, for there is not a tree to be seen; nevertheless, the roots of very large trees, which have been cut by the ax, are found in different places. There is likewise a small grove of birch and hazle on the south-west side of Loch-Stornaway.

The inhabitants of Lewis are well-proportioned, tall, fair, sanguine, strong, and healthy. They are in general sober, circumspect, and hospitable; dexterous in shooting, swimming, and leaping; bold and skilful mariners; and so temperate, that they will tug at the oar all day, without any other provision than bread and water, with a snuff of tobacco.

Along this coast we see several natural mounts or forts, called *Dun*; such as Dun-rowly, Dun-coradel, and Dun-eisten. There are also the remains of some old castles, and other monuments of antiquity. At Stornaway village we see the ruins of a fortress destroyed by the English garrison sent thither by Oliver Cromwell. To the northward of Brago there is a round tower built of large stones, three stories high, tapering towards the top, with a double wall, and a circular staircase between, by which one may go quite round the building. On the heaths and summits of hills there are several cairns or heaps of stones, which served either for graves or beacons. In the parish of Barvas we see a single stone called the *thryshel*, standing upright, above 20 feet high, and almost as much in breadth. Three stones, about 12 feet high each, are seen standing on the north side of Loch-carlavy; and many others standing single at great distances, and in remote parts of the island. But the most remarkable monument of this kind appears by the village of Clafernish. Here we find 39 pyramidal stones standing upright, about six or seven feet high from the surface, each about two feet in breadth. They are placed in form of an avenue, eight feet wide; the distance between every stone amounting to six feet, and a single piece stands at the entrance. This avenue leads to a circle of 12 stones of the same dimensions, with one in the centre 13 feet in length, and shaped like a rudder: on the east, south, and west sides of this circle, are four stones, such as those that compose this round and avenue, forming three lines, or as it were rays from the body of the circle. This is supposed to have been a Druid temple; and tradition reports, that the chief Druid stood by the large stone in the centre, and harangued the audience. At the distance of a quarter of a mile there is another circle of the same nature; but without the range and avenue

Lewis.

In all probability, these, as well as the monuments we have described in our account of the Orkneys, and Stone-henge on Salisbury-plain, were places of worship erected by the Druids in time of Pagan superstition. The chief town in Lewis is called Stornaway.

There is a considerable number of inferior adjacent isles and rocks, some of which hardly deserve to be mentioned; such as the small island Garve at the mouth of Loch Carlavy, Berinsay, Fladda, Bernera Minor, and Bernera Major, Kiallisy, Cayay, Carvay, Grenim, Pabay, Shirem, Vexay, Wuya the Larger and Lesser, and the Flannan islands, which the seamen denominate the *northern hunters*. These are visited every summer by the inhabitants of the Lewis, who go thither in quest of fowls, eggs, down, quills, and feathers, as well as to shear or kill the sheep that are kept here for pasture. As these islands are very steep and rocky, the visitors, after having landed and climbed up the rock by a ladder, uncover their heads, and, making a turn sun-ways, thank God for having escaped the danger they have undergone. In the largest island are the ruins of a chapel dedicated to St Flannan, from whom the isles derive their name. Thither the fowlers repairing, strip themselves of their upper garments, which being laid upon a stone, they advance towards the altar, and repeat three prayers; an exercise which is performed every morning and evening. They observe many other superstitious customs during their residence on these rocks; and when they have landed their boat with their purchase, return to the larger islands. Among the islands belonging to the Lewis, we may likewise take notice of the small isle of Pigmies, so called, because bones resembling those of human creatures, but of very small dimensions, have been dug out of the ground.

The island of Lewis is divided into the two parishes of Barvas and Eye, and in each of these one minister is settled; but there is a great number of churches and chapels dedicated to different saints, in the different isles which compose this cluster. All these were sanctuaries before the reformation, but now they are divested of that privilege. The people of these islands are Presbyterians, with a few Protestants of the English communion, and a still smaller number of Roman Catholics. The Protestants observe the festivals of Christmas, Good Friday, Easter, and Michaelmas; on the last of which the individuals of both sexes perform an anniversary cavalcade.

LEWIS, or LOUIS, the name of several kings of France. See ERANCE.

LEWIS VII. anno 1137, was the first who had the courage to oppose the encroachments of the popes on the regal authority: Pope Innocent II. excommunicated him for appointing an archbishop of Bourges; but Lewis defended his prerogatives, and put the priests to death who had been the authors of the quarrel. In 1147, he put himself at the head of an army of 80,000 men, and marched against the Saracens, in the second crusade, but was defeated; and returning into France by sea, was taken by the Greeks, but rescued by Roger king of Sicily. His queen Eleonora accompanied him in this expedition; and being suspected of infidelity with Saladin, a young Turk,

Lewis.

Lewis.

Lewis divorced her, and she was married six weeks after to Henry duke of Normandy, (Henry II. king of England). Lewis died in 1180, aged 60.

Lewis IX. anno 1226 (canonized), was one of the greatest monarchs of France; equally memorable for his valour and his virtues, but unfortunately misled by the superstition of the times: he sacrificed his own repose, and the welfare of his kingdom, to the folly of crusading. In 1248, leaving France to the care of his mother, he embarked for Egypt, attended by his queen, his three brothers, and the flower of the French nobility. At first his victories were rapid: he took Damietta in 1249; but the following year he was defeated and taken prisoner by the Turks, with all the nobility in his train, and the greatest part of his army. The sultan sent to him in prison, to demand an exorbitant sum for his ransom; and his answer being truly noble, deserves to be recorded: "Tell the sultan, that a king of France is not to be ransomed with money; I will give the sum required for my people, and Damietta for myself." These terms were accepted, and a peace of ten years ensued. Upon his return to France, he diminished the taxes, revoked those which the cupidity of the financiers had introduced; issued several salutary edicts; founded several churches and hospitals; and effectually overturned the ecclesiastical jurisdiction of the court of Rome, by his pragmatic sanction in 1269, which established the independency of the Gallican church. Thirteen years residence in his capital indemnified his subjects for his absence; but his pious zeal prevented the enjoyment of this happiness: he embarked for the sixth crusade in 1270; and died the same year, at the siege of Tunis, aged 55.

Lewis XI. anno 1461. His oppressions obliged his subjects to enter into a league against him, styled "*Ligue de bien public*," in which his brother the duke of Berri and some of the principal nobility were concerned: they solicited succours from John duke of Calabria, who joined them with 500 Swifs (the first introduction of Swifs soldiers into the French armies.) His reign was almost one continued scene of civil war; and it is computed that 4000 of his subjects were executed in public and privately, either for being in arms against him, or suspected by him. In his last illness, he drank the warm blood of children, in the vain hope of restoring his decayed strength. He died in 1483, aged 60. The posts for letters were established in his reign, owing to his eagerness for news; the first institution of this nature in Europe.

Lewis XII. anno 1492, styled the *Just*, and the *Father of his people*; memorable for his valour in the field, and his wisdom in the cabinet. A great general; but unfortunate towards the end of his reign, when he did not command his troops in person: his orders transmitted from home were misunderstood, or wilfully disobeyed; and he had the mortification, before he died, to see the total expulsion of the French from the possessions he had acquired for them by his personal bravery. At 53 years of age, he married the princess Mary of England, sister of Henry VIII. and being of a delicate constitution, fell a victim (according to the French historians) to amorous dalliance; for he died in about two months after his nuptials, in 1515.

Lewis XIII. anno 1610, increased the military reputation of his country, and made considerable additions to its domains. The beginning of his reign was occupied in civil wars with his mother and his Protestaut subjects; in which he was excited to continue by his famous minister cardinal Richelieu, who attended him to the siege of Rochelle, the bulwark of the Huguenot party. This place was reduced by famine to surrender, in 1628, after a siege of more than a year. Upon this and other occasions, the king gave proofs of great personal bravery. His attachment to his ally the duke de Nevers, who succeeded to the duchy of Mantua, but was refused the investiture by Charles VI. emperor of Germany, involved him in a war with that prince, the Spaniards, and the duke of Savoy; in which Lewis was victorious; and obtained a treaty of peace, by which the duke of Mantua was guaranteed in the possession of his dominions. In 1635, a new war broke out between France and Spain, and the emperor took part with the latter: it lasted 13 years against the emperor, and 25 against Spain, with various success; and the different armies kept on foot, in the Low Countries, on the frontiers of France, and in Italy, in the first years of this war, paved the way for the signal successes of Lewis XIV. the campaigns of these armies being a military school of discipline and experience for the French officers, besides giving them a knowledge of the countries which became the seat of war in the next reign. Lewis XIII. died 1643, aged 41.

Lewis XIV. le Grand (king at five years of age), anno 1643. He was at first styled *Dieu-donne*, because the French considered him as the gift of heaven, granted to their prayers after the queen had been barren 22 years. This princess (Anne of Austria) was declared regent by Lewis XIII. and saw herself under a necessity to continue the war against Philip IV. king of Spain, her brother. The duke d'Enguin was made general of the French armies; and so signal was the success of this renowned warrior (afterwards prince of Condé, and known by the style of the *Great Condé*), that his victories brought on the advantageous treaties of Munster in 1648, between France, the emperor Ferdinand III. and Christina queen of Sweden: the basis of the aggrandisement of France in this reign; the principal events of which, and of the next, are related under the articles *BRITAIN, UNITED PROVINCES, &c.* Lewis XIV. died in 1715, aged 77.

Lewis XV. (his great-grandson) succeeded in 1715. He was styled, in the course of his reign, the *well beloved*, which he lost some years before he died; and was detested and despised by his subjects for his shameful attachment to a young girl, under the title of his *mistress*, who, by the ministry of her patron the duke d'Aiguillon, governed the kingdom, and invaded the ancient rights and privileges of the people. He died in 1774, in the 64th year of his age and 59th of his reign.

LEXINGTON, a town of North America, and capital of Kentucky. It stands on the head waters of Elkhorn river, is reckoned the capital of Kentucky. Here the courts are held, and business regularly conducted. In 1786, it contained about 100 houses and several stores, with a good assortment of dry goods. It must have greatly increased since.

LEX, LAW. See LAW.—The Roman laws were of

Lewis.

Lex.

of three kinds: 1st, Such as were made by their kings. 2d, The laws of the twelve tables brought by the *Decemviri* from Athens, &c. And, 3d, Such as were proposed by the superior magistrates in the times of the republic. The laws of this last class were enacted in the following manner.

No law could be proposed but by some of the following magistrates, viz. the *Prator*, the *Consuls*, the *Didactor*, the *Interrex*, the *Decemviri*, the *Military Tribunes*, *Triumviri*, and *Tribunes* of the people. If any of these proposed a law, it was first committed to writing, and privately examined as to its utility and probable consequences, by some persons well qualified for the task; sometimes it was referred to the whole senate for their sentiments. It was then hung up publicly for three market-days, that all the people might have time to examine it, and consider its tendency: This was called *legis promulgatio*, *quasi promulgatio*. If the person who framed the bill did not see cause in the mean time to drop it, the people were convened in *comitia*, and he addressed them in an oration, being also seconded by his friends, setting forth the expediency and probable utility of such a law: This was called *rogatio legis*, because the address was always prefaced with this petitionary form of words, *Vultis iubeatisne, Quirites?* "Will you, O Romans, consent and order this law to pass?" This being done, those that disliked the motion delivered their sentiments in opposition to it. An urn was then brought to certain priests who attended upon the occasion, into which were cast the names of the tribes, centuries, or *curia*, as the *comitia* happened to be *tributa*, *centuriata*, or *curiata*. The names were shaken together; and the first drawn tribe or century was called *prærogativa*, because their suffrages were first taken. The *curia* that was first drawn was called *principium* for the same reason. The other tribes, centuries, &c. were called *tribus jure vocata*, *centuria jure vocata*, &c.

Matters being in this situation, the *velo* or negative voice of the tribunes of the people might put an entire end to the proceedings, and dissolve the assembly. The tribune's interference was called *intercessio*. The consul also had it in his power to stop further proceedings, by commanding any of the holidays called *ferie imperatorie* to be observed. The *comitia* would of course be dissolved also by any of the persons present being seized with the falling-sickness, or upon the appearance of any unlucky omen. But supposing the business to meet with no interruption of this sort, the people were each of them presented with two tablets, on one of which was written in large characters A. on the other U. R. Their disapprobation of the bill was expressed by throwing into an urn the tablet inscribed A. signifying "I forbid it," *antiquo*, "I prefer the old." Their assent was signified by throwing in the tablet marked U. R. i. e. *uti rogas*, "be it as you desire." According to the majority of these tablets the law passed or not. If it passed, it was written upon record, and carried into the treasury; this was called *legem ferre*. Afterwards it was engraved upon plates of brass, and hung up in the most public and conspicuous places: this was termed *legem figere*, and a future repeal of this law was *legem rescire*.

If a law passed in the *comitia curiata*, it was called
Vol. X. Part I.

lex curiata; if in the *comitia centuriata*, it had the name of *lex centuriata*; but if it passed in the *comitia tributa*, it was termed *plebiscitum*. The laws, too, generally bore the names of the proposers, as *lex Ælia*, *lex Folia*, &c.

Romulus used to make laws by his own single authority, but succeeding kings fought the approbation of the people.

LEXIARCHI, at Athens, six officers assisted by 30 inferior ones, whose business it was to lay fines upon such as came not to the public assemblies, and also to make scrutiny among such as were present.

The *lexiarchi* kept a register of the age, manners, and abilities of all the citizens, who were always enrolled at the age of 20.

LEXICON, the game with dictionary. The word is chiefly used in speaking of Greek dictionaries: it is derived from the Greek *λέγειν*, word, *dictio*; of *λέγω* I speak.

LEYDEN, in Latin *Lugdunum Batavorum*, one of the largest and finest cities in Holland, abounds with canals, along which are rows of lofty trees that afford very pleasant walks. An arm or small branch of the Rhine runs through it. Over the canals are 145 bridges, most of them of stone or brick. The university here is the oldest in the United Provinces: it has large privileges; a library well furnished, and particularly rich in manuscripts; a physic-garden well stocked with all sorts of plants, many of which have been brought from the Cape of Good Hope and the East Indies; an anatomy-hall, well provided with skeletons; and an observatory. The professors, who are generally very eminent, read public lectures four times a week, for which they take no money, but about three guineas are paid for a course of private lectures, which lasts a whole year. The students have no distinct habit, but all wear swords, though they generally go to the public and private lectures in their night-gowns and slippers. The salaries of the professors are from 100*l.* to 200*l.* a-year: they wear gowns only when they preside at public disputations, read public lectures, or meet in the senate; and their lectures are always in Latin. The students do not lodge in the university, but where they please in the town. The cloth manufacture here is much decayed, which formerly flourished to such a degree, that 100,000 pieces, it is said, have sometimes been made in a year. The city is famous for the long and severe siege it maintained in 1573 against the Spaniards. We cannot help mentioning the reply of that illustrious magistrate, Adrian de Voss, when the citizens represented to him the havoc made by the famine during the siege, and insisted upon his surrendering: "Friends (said he), here is my body, divide it among you to satisfy your hunger, but banish all thoughts of surrendering to the cruel and perfidious Spaniard." They took his advice, in regard to their not surrendering, and never would listen to any overtures; but told the Spaniards, they would hold out as long as they had one arm to eat and another to fight. There are some fine churches here, and many long, broad, handsome, streets; but the Papists, as at Haerlem, are more numerous than the Protestants.

LEYDEN Phial, a phial coated on the inside and outside with tinsol, or other proper conducting substance,
C. and

Lexiarchi
Leyden.

LEYERA
||
Lhuyd.

and furnished with a brass wire and knob, for giving the electrical shock. See *ELECTRICITY-Index*.

LUCAS was *LEYDEN*. See *LUCAS*.

LEYERA, in botany: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; the pappus paleaceous; that of the disc plumy; the calyx scarious.

LEYTE, one of the Philippine islands in the East Indies, situated in E. Long. 118. O. N. Lat. 11. O. Its greatest length is about 40 leagues, and its circumference about 90 or 100. Its soil on the east side is very fruitful; but there are very high mountains which cut it almost through the middle, and occasion so great an alteration in the air, that when it is winter on the north side, it is summer on the southern part of the island. Thus when the inhabitants of one half of the island reap, the others sow; and they have two plentiful harvests in a year, to which the rivers running down from the abovementioned mountains contribute not a little. The island contains about 9000 inhabitants, who pay tribute to the Spaniards in rice, wax, and quilts.

LHUYD, or **LHOYD** (Humphrey), a learned antiquarian of the 16th century, born at Denbigh, who applied himself to the study of physic; and living mostly within the walls of Denbigh castle, practised there as a physician; and died in 1570, with the character of a well-bred gentleman. He wrote and translated several pieces relative to history and antiquities; in particular, The history of Cambria, now called *Wales*, from Cardoc of Llangarvan, &c. but died before it was finished; however, Sir Henry Sidney, lord president of Wales, employed Dr David Powel to finish it, who published it in 1584. A new and improved edition of this work was published in 1774.

LHUYD (Edward), keeper of the Museum at Oxford, was a native of South Wales, the son of Charles Lhuyd, Esq; of Llanvorde. He was educated at Jesus College, Oxford, where he was created M. A. July 21. 1701. He was bred under Dr Plot, whom he succeeded as keeper of the Ashmolean museum, and had the use of all Vaughan's collections. With incessant labour and great exactness he employed a considerable part of his life in searching into the Welsh antiquities; had perused or collected a great deal of ancient and valuable matter from their MSS.; transcribed all the old charters of their monasteries that he could meet with; travelled several times over Wales, Cornwall, Scotland, Ireland, Armoric Bretagne, countries inhabited by the same people, compared their antiquities, and made observations on the whole; but died in July 1709, before he had digested them into the form of a discourse, as he intended, on the ancient inhabitants of this island. The untimely death of this excellent antiquary prevented the completing of many admirable designs. For want of proper encouragement, he did very little towards understanding the British bards, having seen but one of those of the sixth century, and not being able to procure access to two of the principal libraries in the country. He communicated many observations to Bishop Gibson, whose edition of the *Britannia* he revised; and published "*Archæologia Britannica*, giving some ac-

Lhuyd
||
Libanius.

count additional to what has been hitherto published of the languages, histories, and customs of the original inhabitants of Great Britain, from collections and observations in travels through Wales, Cornwall, Bas Bretagne, Ireland, and Scotland, Vol. I. Glossography, Oxford 1707," fol. He left in MS. a Scottish or Irish-English Dictionary, proposed to be published in 1732 by subscription, by Mr David Malcolm, a minister of the church of Scotland, with additions; as also the Elements of the said language; with necessary and useful informations for propagating more effectually the English language, and for promoting the knowledge of the ancient Scottish or Irish, and very many branches of useful and curious learning. Lhuyd, at the end of his preface to the *Archæologia*, promises an historical dictionary of British persons and places mentioned in ancient records. It seems to have been ready for press, though he could not set the time of publication. His collections for a second volume, which was to give an account of the antiquities, monuments, &c. in the principality of Wales, were numerous and well chosen; but, on account of a quarrel between him and Dr Wynne, then fellow, afterwards principal of the college, and bishop of St Asaph, he refused to buy them, and they were purchased by Sir Thomas Seabright, of Beachwood in Hertfordshire, in whose library the greatest part still remain, but so indigested, and written with so many abbreviations, that nobody can undertake to publish them. They consist of about 49 volumes in folio, 10 in quarto, and above 100 smaller, and all relate to Irish or Welsh antiquities, and chiefly in those languages. Carte made extracts from them about or before 1736; but these were chiefly historical. Sir John Seabright has given Mr Pennant 23 of Lhuyd's MSS. Latin and English. Many of his letters to Lister, and other learned contemporaries, were given by Dr Fothergill to the university of Oxford, and are now in the Ashmolean museum. Lhuyd undertook more for illustrating this part of the kingdom than any one man besides ever did, or than any one man can be equal to.

LIBANIUS, a famous Greek rhetorician and sophist in the 4th century, was born at Antioch, and had a great share in the friendship of Julian the Apostate. That prince offered him the dignity of *Præficus Prætorio*; but Libanius refused it, thinking the name of *sophist*, or *professor of eloquence*, much more honourable. There are still extant several of his letters and Greek orations, by which he acquired great reputation; but his style is somewhat affected and obscure. He was a pagan. Basil and Chrysostom were his disciples about the year 360. His letters were published at Amsterdam in 1738; his orations at Venice, 1755.

LIBANOMANTIA, in antiquity, a species of divination performed with frankincense; which, if it presently caught fire, and sent forth a grateful odour, was esteemed a happy omen, and *vice versa*.

LIBANUS, the name of a chain of mountains of Turkey in Asia, which lie between Proper Syria and Palestine, extending from west to east, from the Mediterranean sea as far as Arabia. The summits of these mountains are so high, that they are always covered with snow; but below are very pleasant, and fruitful.

Libation
 Il
 Label.

Libella

fruitful valleys. They were formerly famous for the great number of cedar-trees growing thereon; but now there are very few remaining. Geographers distinguish this chain into Libanus and Antilibanus; the latter of which lies on the south side of the valley, rising near the ruins of Sidon, and terminates at others in Arabia, in N. Lat. 34. They are separated from each other at an equal distance throughout; and form a basin, or country, called by the ancients *Celo Syria*.

LIBATION, amongst the Greeks and Romans, was an essential part of solemn sacrifices. It was also performed alone, as a drink offering, by way of procuring the protection and favour of the gods, in the ordinary affairs of life. Libations, according to the different natures of the gods in honour of whom they were made, consisted of different liquids, but wine was the most usual. The wine offered to the gods was always unmixed with water. We meet with libations of water, libations of honey, libations of milk, and libations of oil; these are called *σπονδαίαια*. The libation was made with a serious deportment and solemn prayer. At sacrifices, the libation, after it had been tasted by the priest, and handed to the bystanders, was poured upon the victim. At entertainments, a little wine was generally poured out of the cup, before the liquor began to circulate, to show their gratitude to the gods for the blessings they enjoyed.

Libations were also in use among the Hebrews, who poured an hin of wine on the victim after it was killed, and the several pieces of the sacrifice were laid on the altar, ready to be consumed in the flames.

LIBAW, a sea-port town of Courland, lying on the Baltic sea, consisting entirely of wooden houses. It belongs to the duke of Courland, and is situated in E. Long. 21. 27. N. Lat. 56. 27.

LIBEL, (*libellus famosus*), taken in its largest and most extensive sense, signifies any writing, picture, or the like, of an immoral or illegal tendency; but, in a peculiar sense, is used to denote a malicious defamation of any person, and especially a magistrate, made public by either printing, writing, signs or pictures, in order to provoke him to wrath, or expose him to public hatred, contempt, and ridicule. The direct tendency of these libels is the breach of the public peace, by stirring up the objects of them to revenge, and perhaps to bloodshed. The communication of a libel to any one person is a publication in the eye of the law: and therefore the sending an abusive private letter to a man is as much a libel as if it were openly printed, for it equally tends to a breach of the peace.

With regard to libels in general, there are, as in many other cases, two remedies; one by indictment, and another by action. The former for the public offence; for every libel has a tendency to break the peace, or provoke others to break it: which offence is the same whether the matter contained be true or false; and therefore the defendant, on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and show that the plaintiff has received no injury at all. What was said with regard to words spoken, will also

hold in every particular with regard to libels by writing or printing, and the civil actions consequent thereupon: but as to signs or pictures, it seems necessary always to show, by proper innuendoes and averments of the defendant's meaning, the import and application of the scandal, and that some special damage has followed; otherwise it cannot appear, that such libel by picture was understood to be levelled at the plaintiff, or that it was attended with any actionable consequences.

In a civil action, then, a libel must appear to be false, as well as scandalous; for, if the charge be true, the plaintiff has received no private injury, and has no ground to demand a compensation for himself, whatever offence it may be against the public peace: and therefore, upon a civil action, the truth of the accusation may be pleaded in bar of the suit. But, in a criminal prosecution, the tendency which all libels have to create animosities, and to disturb the public peace, is the sole consideration of the law. And therefore, in such prosecutions, the only points to be considered are, first, the making or publishing of the book or writing; and, secondly, whether the matter be criminal: and, if both these points are against the defendant, the offence against the public is complete. The punishment of such libellers, for either making, repeating, printing, or publishing the libel, is a fine, and such corporal punishment as the court in its discretion shall inflict; regarding the quantity of the offence, and the quality of the offender. By the law of the twelve tables at Rome, libels, which affected the reputation of another, were made a capital offence: but, before the reign of Augustus, the punishment became corporal only. Under the emperor Valentinian it was again made capital, not only to write, but to publish, or even to omit destroying them. Our law, in this and many other respects, corresponds rather with the middle age of Roman jurisprudence, when liberty, learning, and humanity, were in their full vigour, than with the cruel edicts that were established in the dark and tyrannical ages of the ancient decemviri, or the latter emperors.

In this, and other instances, where blasphemous, immoral, treasonable, schismatical, seditious, or scandalous libels are punished by the English law, some with a greater, others with a less degree of severity; the *liberty of the press*, properly understood, is by no means infringed or violated. See *LIBERTY of the Press*.

LIBELLA, a piece of money amongst the Romans, being the tenth part of the denarius, and equal in value to the as. It was called *libella*, as being a little pound, because equal to a pound of brass. Its value in our money is 1 ob. 1 qu. or a half-penny farthing. See *MONEY*.

LIBELLA, or *Libellula*, in zoology, a genus of four-winged flies, called in English *dragon flies*, or *adder flies*; the characters of which are these: The mouth is furnished with jaws: the feelers are shorter than the breast; and the tail of the male terminates in a kind of hooked forceps. There are 21 species, chiefly distinguished by their colour. They have all two very large and reticulated eyes, covering the whole surface of the head. They fly very swiftly; and prey upon the wing, clearing the air of innumerable

Plate
 CCLXXIV

L'belli,
Liber.

able little flies. They are found in August and September in our fields and gardens, especially near places where there are waters, as they have their origin from worms living in that element. The great ones usually live all their time about waters; but the smaller are common among hedges, and the smallest of all frequent gardens. The smaller kind often settle upon bushes, or upon the ground; but the large ones are almost always upon the wing, so that it is very difficult to take them. Their eyes are beautiful objects for the microscope. The largest species is produced from a water-worm that has six feet, which, yet young and very small, is transformed into a chrysalis, that has its dwelling in the water. People have thought they discovered there to have gills like fishes. It wears a mask as perfectly formed as those that are worn at a masquerade; and this mask, fastened to the insect's neck, and which it moves at will, serves it to hold its prey while it devours it. The period of transformation being come, the chrysalis makes to the water-side, undertakes a voyage in search of a convenient place; fixes on a plant, or sticks fast to a bit of dry wood. Its skin, grown parched, splits at the upper part of the thorax. The winged insect issues forth gradually, throws off its slough, expands its wings, flutters, and then flies off with gracefulness and ease. The elegance of its slender shape, the richness of its colours, the delicacy and resplendent texture of its wings, afford infinite delight to the beholder. The sexual parts of the libellule are differently situated in the male and female. It is under the body at the joining of the thorax, that those parts are discovered in the males: those of the females are known by a slit placed at the extremity of the body. Their amours conclude in a rape. The male, while hovering about, watches, and then seizes the female by the head with the pincers with which the extremity of his tail is armed. The ravisher travels thus through the air, till the female yielding to superior strength, or rather to inclination, forms her body into a circle that terminates at the genitals of the male, in order to accomplish the purpose of nature. These kind of rapes are common. Libellule are seen thus coupled in the air, exhibiting the form of a ring. The female deposits her eggs in the water, from whence spring water-worms, which afterwards undergo the same transformations.

LIBELLI, was the name given to the bills which were put up amongst the Romans, giving notice of the time when a show of gladiators would be exhibited, with the number of combatants, and other circumstances. This was called *munus pronunciare* or *proponere*.—These bills were sometimes termed *edicta*. These public notices were given by the person who designed to oblige the people with the show, and were frequently attended with pictures representing the engagement of some celebrated gladiators. This custom is alluded to by Horace, lib. ii. sat. vii. v. 96, &c.

There was also the *fameus libellus*, a defamatory libel. Seneca calls them *contumeliosi libelli*, infamous rhymes, which by a Roman ordinance were punishable with death. Libellus also in the civil law signifies the declaration, or state of the prosecutor's charge against the defendant; and it has the like signification in our spiritual courts.

LIBER, in vegetables, the bark or rind, princi-

pally of trees. This is to be conceived as consisting of a number of cylindric and concentric surfaces whose texture is reticular, and in some trees plainly extrusible every way, by reason that the fibres are soft and flexible. While in this condition, they are either hollow regular canals, or, if not so, they have interstitial spaces which serve the office of canals. The nutritious juice which they are continually receiving, remains in part in them; makes them grow in length and thickness, and strengthens and brings them closer together; and by this means the texture which was before reticular becomes an assemblage of straight fibres ranged vertically and parallel to each other; that is, as they are thus altered behind one another, they by degrees become a new substance, more woody, called *blea*.

LIBERA, in mythology, the name of a goddess, which Cicero, in his book Of the Gods, represents as the daughter of Jupiter and Ceres. Ovid in his *Fasts* says that the name was given by Bacchus to Ariadne.

Libera is exhibited on medals as a kind of female Bacchus, crowned with vine leaves.

LIBERAL ARTS, are such as depend more on the labour of the mind than on that of the hands; or, that consist more in speculation than operation; and have a greater regard to amusement and curiosity than to necessity.

The word comes from the Latin *liberalis*, which among the Romans, signified a person who was not a slave; and whose will, of consequence, was not checked by the command of any master.

Such are grammar, rhetoric, painting, sculpture, architecture, music, &c. The liberal arts used formerly to be summed up in the following Latin verse: *Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra*. And the mechanical arts, which, however, are innumerable, under this:

Rus, Nemus, Arma, Faber, Vulnera, Luna, Rater.

See **ARTS**.

LIBERALIA, feasts celebrated by the ancient Romans, in honour of Liber or Bacchus, the same with those which the Greeks called *DIONYSIA*, and *Dionysia*.

They took their name from *liber*, i. e. *free*, a title conferred on Bacchus in memory of the liberty or freedom which he granted to the people of Bœotia; or, perhaps, because wine, whereof he was the reputed deity, delivers men from care, and sets their mind at ease and freedom. Varro derives the name of this feast from *liber*, considered as a noun adjective; and signifying *free*; because the priests were free from their function, and eased of all care, during the time of the *liberalia*: as the old women officiated in the ceremonies and sacrifices of these feasts.

LIBERIA, in Roman antiquity, a festival observed on the 16th of the kalends of April, at which time the youth laid aside their juvenile habit for the toga virilis, or habit peculiar to grown men. See the article **TOGA**.

LIBERTINES, **LIBERTINI**, in ecclesiastical history, a religious sect, which arose in the year 1525, whose principal tenets were, that the Deity was the sole operating cause in the mind of man, and the immediate author of all human actions; that, consequently, the distinctions of good and evil, which had been established with regard to those actions, were false and groundless, and

Libera
||
Libertines.

Libertines, and that men could not, properly speaking, commit sin; that religion consisted in the union of the spirit or rational soul with the Supreme Being; that all those who had attained this happy union, by sublime contemplation and elevation of mind, were then allowed to indulge, without exception or restraint, their appetites or passions; that all their actions and pursuits were then perfectly innocent; and that, after the death of the body, they were to be united to the Deity. They likewise said that Jesus Christ was nothing but a mere *je ne sçai quoi*, composed of the spirit of God, and of the opinion of men.

These maxims occasioned their being called *Libertines*; and the word has been used in an ill sense ever since.

The *Libertini* spread principally in Holland and Brabant. Their leaders were one Quintin, a Picard, Pockefius, Ruffius, and another called Chopin, who joined with Quintin, and became his disciple.

This sect obtained a certain footing in France thro' the favour and protection of Margaret, queen of Navarre, and sister to Francis I. and found patrons in several of the reformed churches. This sect was probably a remnant of the more ancient Beguards or Brethren of the Free Spirit.

LIBERTINES of Geneva, were a cabal of rakes rather than of fanatics; for they made no pretences to any religious system, but pleaded only for the liberty of leading voluptuous and immoral lives. This cabal was composed of a certain number of licentious citizens, who could not bear the severe discipline of Calvin, who punished with rigour not only dissolute manners, but also whatever bore the aspect of irreligion and impiety. In this turbulent cabal there were several persons who were not only notorious for their dissolute and scandalous manner of living, but also for their atheistical impiety, and contempt of all religion. To this odious class belonged one Gruet, who denied the divinity of the Christian religion, the immortality of the soul, the difference between moral good and evil, and rejected with disdain the doctrines that are held most sacred among Christians; for which impieties he was at last brought before the civil tribunal, in the year 1550, and condemned to death. The Genevan spirit of reformation, improperly directed by the violence and zeal of Calvin, did at this time operate to a degree which has marked the character of this great reformer with reproach. For in 1544, Sebastian Castillo, master of the public school at Geneva, who was a man of probity, and distinguished by his learning and taste, was, nevertheless, deposed from his office and banished the city, because he disapproved some of the measures that were pursued and some of the opinions entertained by Calvin and his colleagues, and particularly that of absolute and unconditional predestination. Jerome Bolsee also, a man of genius and learning, who became a convert to the Protestant religion and fled to Geneva for protection, was cast into prison, and soon after sent into banishment, because, in 1551, he imprudently and inconsiderately declaimed, in full congregation and at the close of public worship, against the doctrine of absolute decrees.

LIBERTUS, or **LIBERTINUS**, among the Romans, a freedman, or a person set free from a legal servitude.

These still retained some mark of their ancient state: he who made a slave free having a right of patronage over the *libertus*; so that if the latter failed of showing due respect to his patron, he was restored to his servitude; and if the *libertus* died without children, his patron was his heir. See **SLAVE**.

In the beginning of the republic, *libertinus* denoted the son of a *libertus* or freedman; but afterwards, before the time of Cicero, and under the emperors, the terms *libertus* and *libertinus*, as Suetonius has remarked, were used as synonymous.

LIBERTY, denotes a state of freedom, in contradistinction to *slavery* or *restraint*; and may be considered as either *natural* or *civil*.

The absolute rights of man, considered as a free agent, endowed with discernment to know good from evil, and with power of choosing those measures which appear to him to be most desirable, are usually summed up in one general appellation, and denominated the *natural liberty of mankind*. This natural liberty consists properly in a power of acting as one thinks fit, without any restraint or controul, unless by the law of nature; being a right inherent in us by birth, and one of the gifts of God to man at his creation, when he endued him with the faculty of free-will. But every man, when he enters into society, gives up a part of his natural liberty, as the price of so valuable a purchase; and, in consideration of receiving the advantages of mutual commerce, obliges himself to conform to those laws which the community has thought proper to establish. And this species of legal obedience and conformity is infinitely more desirable than that wild and savage liberty which is sacrificed to obtain it. For no man, that considers a moment, would wish to retain the absolute and uncontrouled power of doing whatever he pleases: the consequence of which is, that every other man would also have the same power; and then there would be no security to individuals in any of the enjoyments of life.

Political, therefore, or *civil*, liberty, which is that of a member of society, is no other than natural liberty, so far restrained by human laws (and no farther) as is necessary and expedient for the general advantage of the public. Hence we may collect, that the law, which restrains a man from doing mischief to his fellow citizens, though it diminishes the natural, increases the civil liberty of mankind: but every wanton and causeless restraint of the will of the subject, whether practised by a monarch, a nobility, or a popular assembly, is a degree of tyranny. Nay, that even laws themselves, whether made with or without our consent, if they regulate and constrain our conduct in matters of mere indifference, without any good end in view, are laws destructive of liberty: whereas, if any public advantage can arise from observing such precepts, the controul of our private inclinations, in one or two particular points, will conduce to preserve our general freedom in others of more importance, by supporting that state of society which alone can secure our independence. Thus the statute of king Edward IV. which forbade the fine gentlemen of those times (under the degree of a lord) to wear pikes upon their shoes or boots of more than two inches in length, was a law that favoured of oppression; because, how-

Liberty.

ever ridiculous the fashion then in use might appear, the restraining it by pecuniary penalties could serve no purpose of common utility. But the statute of King Charles II. which prescribes a thing seemingly as indifferent, *viz.* a dress for the dead, who were all ordered to be buried in woollen, is a law consistent with public liberty; for it encourages the staple trade, on which in great measure depends the universal good of the nation. So that laws, when prudently framed, are by no means subversive, but rather introductive, of liberty; for (as Mr Locke has well observed) where there is no law there is no freedom. But then, on the other hand, that constitution or frame of government, that system of laws, is alone calculated to maintain civil liberty, which leaves the subject entire master of his own conduct, except in those points wherein the public good requires some direction or restraint.

The idea and practice of this political or civil liberty flourish in their highest vigour in these kingdoms, where it falls little short of perfection, and can only be lost or destroyed by the folly or demerits of its owner; the legislature, and of course the laws of Britain, being peculiarly adapted to the preservation of this inestimable blessing even in the meanest subject. Very different from the modern constitutions of other states on the continent of Europe, and from the genius of the imperial law; which in general are calculated to vest an arbitrary and despotic power, of controuling the actions of the subject, in the prince, or in a few grandees. And this spirit of liberty is so deeply implanted in our constitution, and rooted even in our very soil, that a slave or a negro, the moment he lands in Britain, falls under the protection of the laws, and so far becomes a freeman; though the master's right to his service may possibly still continue.

The absolute rights of every Briton (which, taken in a political and extensive sense, are usually called their *liberties*), as they are founded on nature and reason, so they are covel with our form of government; though subject at times to fluctuate and change, their establishment (excellent as it is) being still human. At some times we have seen them depressed by overbearing and tyrannical princes; at others, so luxuriant as even to tend to anarchy, a worse state than tyranny itself, as any government is better than none at all. But the vigour of our free constitution has always delivered the nation from these embarrassments: and, as soon as the convulsions consequent on the struggle have been over, the balance of our rights and liberties has settled to its proper level; and their fundamental articles have been from time to time asserted in parliament, as often as they were thought to be in danger:

First, by the great charter of liberties, which was obtained, sword in hand, from King John, and afterwards, with some alterations, confirmed in parliament by King Henry III. his son. Which charter contained very few new grants; but, as Sir Edward Coke observes, was for the most part declaratory of the principal grounds of the fundamental laws of England. Afterwards, by the statute called *confirmatio cartarum*, whereby the great charter is directed to be allowed as the common law; all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a-year to the people; and sentence of excommunication is directed to

be as constantly denounced against all those that by word, deed, or counsel, act contrary thereto, or in any degree infringe it. Next by a multitude of subsequent corroborating statutes (Sir Edward Coke reckons 32), from the first Edward to Henry IV. Then, after a long interval, by the *petition of rights*; which was a parliamentary declaration of the liberties of the people, assented to by King Charles I. in the beginning of his reign. Which was closely followed by the still more ample concessions made by that unhappy prince to his parliament, before the fatal rupture between them; and by the many salutary laws, particularly the *habeas corpus* act, passed under Charles II. To these succeeded the *bill of rights*, or declaration delivered by the lords and commons to the prince and princeps of Orange, 13th February 1688; and afterwards enacted in parliament, when they became king and queen: which declaration concludes in these remarkable words; "and they do claim, demand, and insist upon, all and singular the premises, as their undoubted rights and liberties." And the act of parliament itself recognises "all and singular the rights and liberties asserted and claimed in the said declaration to be the true, ancient, and indubitable rights of the people of this kingdom." Lastly, these liberties were again asserted at the commencement of the present century, in the *act of settlement*, whereby the crown was limited to his present majesty's illustrious house: and some new provisions were added, at the same fortunate era, for better securing our religion, laws, and liberties; which the statute declares to be "the birthright of the people of England," according to the ancient doctrine of the common law.

Thus much for the *declaration* of our rights and liberties. The rights themselves, thus defined by these several statutes, consist in a number of private immunities; which will appear, from what has been premised, to be indeed no other, than either that *residuum* of natural liberty, which is not required by the laws of society to be sacrificed to public convenience; or else those civil privileges, which society hath engaged to provide, in lieu of the natural liberties so given up by individuals. These therefore were formerly, either by inheritance or purchase, the rights of all mankind; but, in most other countries of the world, being now more or less debased and destroyed, they at present may be said to remain, in a peculiar and emphatical manner, the rights of the people of Britain. And these may be reduced to three principal or primary articles; the right of personal security, the right of personal liberty, and the right of private property: because, as there is no other known method of compulsion, or of abridging man's natural free-will, but by an infringement or diminution of one or other of these important rights, the preservation of these inviolate may justly be said to include the preservation of our civil immunities in their largest and most extensive sense. See the article *RIGHTS*.

In vain, however, would these rights be declared, ascertained, and protected by the dead letter of the laws, if the constitution had provided no other method to secure their actual enjoyment. It has therefore established certain other auxiliary subordinate rights of the subject, which serve principally as barriers to protect and maintain inviolate the three great and pri-

mary

Blackst.
Comment.

Liberty.

mary rights, of personal security, personal liberty, and private property. These are,

1. The constitution, powers, and privileges of parliament; for which see PARLIAMENT.

2. The limitation of the king's prerogative, by bounds to certain and notorious; that it is impossible he should exceed them without the consent of the people; as to which, see PREROGATIVE. The former of these keeps the legislative power in due health and vigour, so as to make it improbable that laws should be enacted destructive of general liberty: the latter is a guard upon the executive power, by restraining it from acting either beyond or in contradiction to the laws that are framed and established by the other.

3. A third subordinate right of every Briton is that of applying to the courts of justice for redress of injuries. Since the law is, in this realm, the supreme arbiter of every man's life, liberty, and property, courts of justice must at all times be open to the subject, and the law be duly administered therein. The emphatical words of *magna carta*, spoken in the person of the king, who in judgment of law (says Sir Edward Coke) is ever present and repeating them in all his courts, are these: *Nulli vendemus, nulli negabimus, aut differemus rectum vel iustitiam*; "and therefore every subject (continues the same learned author), for injury done to him in *bonis, in terris, vel persona*, by any other subject, be he ecclesiastical or temporal, without any exception, may take his remedy by the course of the law, and have justice and right for the injury done to him, freely without fee, fully without any denial, and speedily without delay." It were endless to enumerate all the *affirmative* acts of parliament, wherein justice is directed to be done according to the law of the land: and what that law is, every subject knows; or may know if he pleases: for it depends not upon the arbitrary will of any judge; but is permanent, fixed, and unchangeable, unless by authority of parliament. We shall however just mention a few *negative* statutes, whereby abuses, perversions, or delays of justice, especially by the prerogative, are restrained. It is ordained by *magna carta*, that no freeman shall be outlawed, that is, put out of the protection and benefit of the laws, but according to the law of the land. By 2 Edw. III. c. 8. and 11 Ric. II. c. 10. it is enacted, that no commands or letters shall be sent under the great seal, or the little seal, the signet or privy seal, in disturbance of the law; or to disturb or delay common right: and, though such commandments should come, the judges shall not cease to do right: which is also made a part of their oath by statute 18 Edw. III. §. 4. And by 1 W. & M. §. 2. c. 2. it is declared, that the pretended power of suspending or dispensing with laws, or the execution of laws, by regal authority without consent of parliament, is illegal.

Not only the substantial part, or judicial decisions, of the law, but also the formal part, or method of proceeding, cannot be altered but by parliament: for, if once those outworks were demolished, there would be an inlet to all manner of innovation in the body of the law itself. The king, it is true, may erect new courts of justice; but then they must proceed according to the old established forms of the common law. For which reason it is declared in the statute 16 Car. I.

Liberty.

c. 10. upon the dissolution of the court of star-chamber, that neither his majesty, nor his privy-council, have any jurisdiction, power, or authority, by English bill, petition, articles, libel (which were the course of proceeding in the star-chamber, borrowed from the civil law), or by any other arbitrary way whatsoever, to examine, or draw into question, determine, or dispose of the lands or goods of any subjects of this kingdom; but that the same ought to be tried and determined in the ordinary courts of justice, and by *course of law*.

4. If there should happen any uncommon injury, or infringement of the rights before mentioned, which the ordinary course of law is too defective to reach, there still remains a fourth subordinate right, appertaining to every individual, namely, the right of petitioning the king, or either house of parliament, for the redress of grievances. In Russia we are told, that the Czar Peter established a law, that no subject might petition the throne till he had first petitioned two different ministers of state. In case he obtained justice from neither, he might then present a third petition to the prince; but upon pain of death, if found to be in the wrong. The consequence of which was, that no one dared to offer such third petition; and grievances seldom falling under the notice of the sovereign, he had little opportunity to redress them. The restrictions, for some there are, which are laid upon petitioning in Britain, are of a nature extremely different; and while they promote the spirit of peace, they are no check upon that of liberty. Care only must be taken, lest, under the pretence of petitioning, the subject be guilty of any riot or tumult; as happened in the opening of the memorable parliament in 1640: and, to prevent this, it is provided by the statute 13 Car. II. §. 1. c. 5. that no petition to the king, or either house of parliament, for any alteration in church or state, shall be signed by above 20 persons, unless the matter thereof be approved by three justices of the peace, or the major part of the grand jury, in the country; and in London, by the lord mayor, aldermen, and common-council: nor shall any petition be presented by more than 10 persons at a time. But, under these regulations, it is declared by the statute 1 W. & M. §. 2. c. 2. that the subject hath a right to petition; and that all commitments and prosecutions for such petitioning are illegal.

5. The fifth and last auxiliary right of the subject, that we shall at present mention, is that of having arms for their defence, suitable to their condition and degree, and such as are allowed by law. Which is also declared by the same statute 1 W. & M. §. 2. c. 2. and is indeed a public allowance, under due restrictions, of the natural right of resistance and self-preservation, when the sanctions of society and laws are found insufficient to restrain the violence of oppression.

In these several articles consist the rights, or, as they are frequently termed, the *liberties of Britons*: liberties more generally talked of, than thoroughly understood; and yet highly necessary to be perfectly known and considered by every man of rank or property, lest his ignorance of the points whereon they are founded should hurry him into faction and licentiousness on the one hand, or a pusillanimous indiffe-

Liberty.

rence and criminal submission on the other. And we have seen that these rights consist, primarily, in the free enjoyment of personal security, of personal liberty, and of private property. So long as these remain inviolate, the subject is perfectly free; for every species of compulsive tyranny and oppression must act in opposition to one or other of these rights, having no other object upon which it can possibly be employed. To preserve these from violation, it is necessary that the constitution of parliaments be supported in its full vigour; and limits, certainly known, be set to the royal prerogative. And, lastly, to vindicate these rights, when actually violated or attacked, the subjects of Britain are intitled, in the first place, to the regular administration and free course of justice in the courts of law; next, to the right of petitioning the king and parliament for redress of grievances; and, lastly, to the right of having and using arms for self preservation and defence. And all these rights and liberties it is our birthright to enjoy entire; unless where the laws of our country have laid them under necessary restraints. Restraints in themselves so gentle and moderate, as will appear upon farther inquiry, that no man of sense or probity would wish to see them slackened. For all of us have it in our choice to do every thing that a good man would desire to do; and are restrained from nothing, but what would be pernicious either to ourselves or our fellow-citizens. So that this review of our situation may fully justify the observation of a learned French author, who indeed generally both thought and wrote in the spirit of genuine freedom; and who hath not scrupled to profess, even in the very bosom of his native country, that the British is the only nation in the world, where political or civil liberty is the direct end of its constitution. Recommending therefore to the student in our laws a farther and more accurate search into this extensive and important title, we shall close our remarks upon it with the expiring wish of the famous Father Paul to his country, "ESTO PERPETUA!"

LIBERTY and Necessity. See METAPHYSICS.

LIBERTY of the Press. The art of printing, soon after its introduction, was looked upon in England, as well as in other countries, as merely a matter of state, and subject to the coercion of the crown. It was therefore regulated with us by the king's proclamations, prohibitions, charters of privilege and licence, and finally by the decrees of the court of star-chamber, which limited the number of printers, and of presses which each should employ, and prohibited new publications unless previously approved by proper licensers. On the demolition of this odious jurisdiction in 1641, the long parliament of Charles I. after their rupture with that prince, assumed the same powers as the star-chamber had exercised with respect to the licensing of books: and in 1643, 1647, 1649, and 1652 (Scobell. i. 44, 134. ii. 88, 230.) issued their ordinances for that purpose, founded principally on the star-chamber decree of 1637. In 1662, was passed the statute 13 & 14. Car. II. c. 33. which, with some few alterations, was copied from the parliamentary ordinances. This act expired in 1679; but was revived by statute 1 Jac. II. c. 17. and continued till 1692. It was then continued for two years longer by statute 4 W. & M. c. 24. but though frequent attempts were made by the govern-

Nº 181.

ment to revive it, in the subsequent part of that reign (Com. Journ. 11 Feb. 1694. 26 Nov. 1695. 22 Oct. 1696. 9 Feb. 1697. 31 Jan. 1698.) yet the parliament resisted it so strongly, that it finally expired, and the press became properly free in 1694, and has continued so ever since.

The liberty of the press, however, so essential to the nature of a free state, consists not in freedom from censure for any criminal matter that may be published, but in laying no previous restraints upon publications. Every freeman has undoubtedly a right to lay what sentiments he pleases before the public; to forbid this, is to destroy the freedom of the press: but if he publishes what is improper, mischievous, or illegal, he must take the consequence of his own temerity †. To subject the press to the restrictive power of a licenser in the manner above mentioned, is to subject all freedom of sentiment to the prejudices of one man, and make him the arbitrary and infallible judge of all controverted points in learning, religion, and government. But to punish (as the law does at present) any dangerous or offensive writings which, when published, shall, on a fair and impartial trial, be adjudged of a pernicious tendency, is necessary for the preservation of peace and good order, of government and religion, the only solid foundations of civil liberty. Thus the will of individuals is still left free; the abuse only of that free-will is the object of legal punishment. Neither is any restraint hereby laid upon freedom of thought or inquiry; liberty of private sentiment is still left; the disseminating or making public of bad sentiments, destructive of the ends of society, is the crime which society corrects. A man (says a fine writer on this subject) may be allowed to keep poisons in his closet, but not publicly to vend them as cordials. And to this we may add, that the only plausible argument heretofore used for restraining the just freedom of the press, "that it was necessary to prevent the daily abuse of it," will entirely lose its force, when it is shown (by a seasonable exertion of the laws) that the press cannot be abused to any bad purpose without incurring a suitable punishment: whereas, it can never be used to any good one when under the controul of an inspector. So true will it be found, that to censure the licentiousness, is to maintain the liberty of the press.

LIBERTY, in mythology, was a goddess both among the Greeks and Romans. Among the former she was invoked under the title *Eleutheria*; and by the latter she was called *Libertas*, and held in singular veneration; temples, altars, and statues, were erected in honour of this deity. A very magnificent temple was consecrated to her on mount Aventin, by Tiberius Gracchus, before which was a spacious court, called *atrium libertatis*. The Romans also erected a new temple in honour of Liberty, when Julius Cæsar established his empire over them, as if their liberty had been secured by an event which proved fatal to it. In a medal of Brutus, Liberty is exhibited under the figure of a woman, holding in one hand a cap, the symbol of Liberty, and two poinards in the other, with the inscription *LIBERTAS MARTIS*.

LIBETHRA (anc. geog.), the fountain of song, was situated in Magnesia, a district of Macedonia annexed to Thessaly; distinct from the town of Libethra, which stood on the mount Olympus, where it

Liberty.
Libethra.

† See Liberty.

Librius verges towards Macedonia: hence the Muses are called *Libethrides*, (Virgil.) Strabo places on Helicon, not only Hippocrene, and the temple of the Muses, but also the cave of the nymphs Libethrides.

LIBETHRIUS MONS (anc. geog.), a mountain of Boeotia, distant from Coronea 40 stadia; where stood the statues of the Muses, and of the nymphs, surnamed *Libethride*. A mountain probably conjoined with, or at least very near to, Helicon.

LIBITINA, in the Roman mythology, a goddess which presided over funerals. This goddess was the same with the *Venus infera* or *Epithymia* of the Greeks. She had a temple at Rome, where was lodged a certain piece of money for every person who died, whose name was recorded in a register called *Libitina ratio*. This practice was established by Servius Tullius, in order to obtain an account of the number of annual deaths in the city of Rome, and consequently the rate of increase or decrease of its inhabitants.

LIBITINARIUM, were undertakers whose office it was to take care of funerals, prepare all things necessary upon the solemn occasion, and furnish every article required.—They got their livelihood by this gloomy business, and kept a number of servants to perform the working part of the profession, such as the *pollinctores*, *vespillones*, &c. The name *Libitinarium* is derived from *Libitina*, the goddess of funerals, in whose temple were sold all things relating to funerals. See **FUNERAL**.

LIBNA (anc. geog.), a sacerdotal city in the tribe of Judah, a place of strength, as appears from Sennacherib's laying siege to it, 2 Kings xix. Isaiah xxxvii. In Jerome's time, a village, called *Lobna*, in the territory of Eleutheropolis.

LIBOURNE, a town of France, in Guienne, and in Bourdelois. It is a populous trading town, and is seated on the river Dordogne. W. Long. o. 10. N. Lat. 44. 55.

LIBRA, or **BALANCE**, one of the mechanical powers. See **BALANCE**.

LIBRA, in astronomy, one of the 12 signs of the zodiac, and exactly opposite to Aries; so called because when the sun is in this sign at the autumnal equinox, the days and nights are equal as if weighed in a balance.—The stars in this constellation according to Ptolemy are 17, Tycho 10, Hevelius 20, and Flamsteed 51.

LIBRA also denotes the ancient Roman pound, borrowed from the Sicilians, who called it *libra*.

The libra was divided into 12 *uncie* or ounces, and the ounce into 24 scruples.

The divisions of the libra were, the *uncia*, one twelfth; the *sextans*, one sixth; the *quadrans*, one fourth; the *triens*, one third; the *quincunx*, five ounces; the *semis*, six; the *septunx*, seven; the *bes*, eight; the *dodrans*, nine; the *dextrans*, ten; the *denus*, eleven; lastly, the *as* weighed twelve ounces or one libra.

The Roman libra was used in France for the proportions of their coin till the time of Charlemagne, or perhaps till that of Philip I. in 1093, their sols being so proportioned, as that 20 of them were equal to the libra. By degrees it became a term of account; and every thing of the value of twenty sols was called a *livre*.

Vol. X. Part I.

LIBRA pēsa, in our law books, denotes a pound of money in weight. It was usual in former days not only to tell the money but to weigh it: because many cities, lords, and bishops, having their mints, coined money, and often very bad too; for which reason, though the pound consisted of 20 shillings, they always weighed it.

LIBRARIUM, among the ancients, were a sort of copyists who transcribed in beautiful or at least legible characters, what had been written by the notarii in notes and abbreviations.

LIBRARY, an edifice or apartment destined for holding a considerable number of books placed regularly on shelves; or the books themselves lodged in it.

Some authors refer the origin of libraries to the Hebrews; and observe, that the care these took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to other nations, particularly to the Egyptians. Osmanduas, king of Egypt, is said to have taken the hint first; who, according to Diodorus, had a library built in his palace, with this inscription over the door, *ἡ τῆς βασιλείας βιβλιοθήκη*. Nor were the Ptolemies, who reigned in the same country, less curious and magnificent in books.

The scripture also speaks of a library of the kings of Persia, Ezra v. 17. vi. 1. which some imagine to have consisted of the historians of that nation, and of memoirs of the affairs of state; but, in effect, it appears rather to have been a depository of laws, charters, and ordinances of the kings. The Hebrew text calls it the *house of treasures*, and afterwards the *house of the rolls*, where the treasures were laid up. We may, with more justice, call that a *library*, mentioned in the second of Esdras to have been built by Nehemiah, and in which were preserved the books of the prophets, and of David, and the letters of their kings.

The first who erected a library at Athens, was the tyrant Pisistratus; and yet Strabo refers the honour of it to Aristotle. That of Pisistratus was transported by Xerxes into Persia, and was afterwards brought back by Seleucus Nicanor to Athens. Long after, it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that under Eumenes there was a library at Pergamus, containing 200,000 books. Tyrannian, a celebrated grammarian, contemporary with Pompey, had a library of 30,000 volumes. That of Ptolemy Philadelphus, according to A. Gellius, contained 700,000, all in rolls, burnt by Caesar's soldiers.

Constantine, and his successors, erected a magnificent one at Constantinople; which in the eighth century contained 300,000 volumes, all burnt by order of Leo Isaurus; and, among the rest, one wherein the Iliad and Odyssey were written in letters of gold, on the guts of a serpent.

The most celebrated libraries of ancient Rome, were the Ulpian, and the Palatine. They also boast much of the libraries of Paulus Æmilius, who conquered Perseus; of Lucilius Lucullus, of Asinius Pollio, Atticus, Julius Severus, Domitius, Serenus, Pamphilus Martyr, and the emperors Gordian and Trajan.

Anciently, every large church had its library; as appears by the writings of St Jerome, Anastasius, and others. Pope Nicholas laid the first foundation of

D

that

Libra
Library.

that of the Vatican, in 1450. It was destroyed by the conftable Bourbon, in the facking of Rome, and reftored by Pope Sixtus V. and has been confiderably enriched with the ruins of that of Heidelberg, plundered by Count Tilly in 1622. One of the moft complete libraries in Europe, was faid to be that erected at Florence by Cofmo de Medicis, over the gate whereof is written, *LABOR ABSQUE LABORE*; though it is now exceeded by that of the French king, begun by Francis I. augmented by Cardinal Richelieu, and completed by M. Colbert.

The emperor's library at Vienna, according to Lambecius, confifts of 80,000 volumes, and 15,940 curious medals.

The Bodleian library at Oxford, built on the foundation of that of Duke Humphry, exceeds that of any univerfity in Europe, and even thofe of all the fovereigns of Europe, except the emperor's and French king's, which are each of them older by 100 years. It was firft opened in 1602, and has fince found a great number of benefactors; particularly Sir Robert Cotton, Sir H. Savil, Archbifhop Laud, Sir Kenelm Digby, Mr Allen, Dr Pococke, Mr Selden, and others. The Vatican, the Medicean, that of Beflarion at Venice, and thofe juft mentioned, exceed the Bodleian in Greek manucripts: which yet outdoes them all in Oriental manucripts.

As to printed books, the Ambrofian at Milan, and that of Wolfenbuttle, are two of the moft famous, and yet both inferior to the Bodleian.

King's LIBRARY, at St James's, was founded by Henry, eldeft fon of James I. and made up partly of books, and partly of manucripts, with many other curiofities, for the advancement of learning. It has received many additions from the libraries of Ifaac Cafaubon and others.

Coltonian LIBRARY, originally confifted of 958 volumes of original charters, grants, inftruments, letters of fovereign princes, tranfactions between this and other kingdoms and ftates, genealogies, hiftories, registers of monafteries, remains of Saxon laws, the book of Genefis, thought to be the moft ancient Greek copy extant, and faid to have been written by Origen in the fecond century, and the curious Alexandrian copy or manucript in Greek capitals. This library is kept in the Britifh Mufeum, with the large and valuable library of Sir Hans Sloane, amounting to upwards of 42,000 volumes, &c. There are many public libraries belonging to the feveral colleges at Oxford and Cambridge, and the univerfities in North Britain. The principal public libraries in London, befide that of the Mufeum, are thofe of the college of heralds, of the college of phyficians, of Doctors Commons, to which every bifhop, at the time of his confecration, gives at leaft 20l. fometimes 50l. for the purchafe of books; thofe of the Gray's Inn, Lincoln's Inn, Inner Temple, and Middle Temple; that of Lambeth, founded by Archbifhop Bancroft in 1610, for the ufe of fucceeding archbifhops of Canterbury, and increafed by the benefactions of Archbifhops Abbot, Sheldon, and Tennifon, and faid to confift of at leaft 15,000 printed books, and 617 volumes in manucript; that of Red-Crofs ftreet, founded by Dr Daniel Williams, a Prefbyterian divine, and fince enriched by many private benefactions; that of the Royal

Society, called the *Arundelion* or *Norfolk library*, becaufe the principal part of the collection formerly belonged to the family of Arundel, and was given to the fociety by Henry Howard, afterwards duke of Norfolk, in 1666, which library has been increafed by the valuable collection of Francis Alton, Efq; in 1715, and is continually increafing by the numerous benefactions of the works of its learned members, and others: that of St Paul's, of Sion college; the queen's library, erected by Queen Caroline in 1737; and the furgeon's library, kept in their hall in the Old Bailey, &c.

In Edinburgh there is a good library belonging to the univerfity, well furnifhed with books; which are kept in good order. There is alfo a noble library of books and manucripts belonging to the faculty of advocates. See *ADVOCATE*.

LIBRATION, in aftronomy, an apparent irregularity of the moon's motion, whereby fhe feems to librate about her axis, fometimes from the eaft to the weft, and now and then from the weft to the eaft. See *ASTRONOMY*, n° 420.

LIBURNIA (anc. geog.), a diftrict of Illyricum, extending towards the Adriatic between Iftria on the weft, Dalmatia on the eaft, and mount Albus on the north. *Liburni*, the people. The apparitors, who at the command of the magiftrate fummoned the people from the country, were called *Liburni*, becaufe generally men of *Liburnia*.—*Liburna*, or *Lilurnica*, (Horace), denoted a kind of light and fwift fkiif, ufed by the Liburnians in their fea-rovings or piracies, for which they were noted. *Liburnum* (Juvenal), was a fpecies of litter made in form of Liburnian fkiiffs, wherein the noblemen of Rome were carried, and where they fat at their eaft, either reading or writing.

LIBURNUS (anc. geog.), a mountain of Campania. Alfo a port of Tufcany. Now *Livorno*, or *Leghorn*. E. Long. 11. N. Lat. 43. 30.

LIBYA, in general, according to the Greeks, denoted Africa. An appellation derived from *hub*, "thirft," being a dry and thirfty country. See *AFRICA*.

LIBYA, in a more reftained fenfe, was the middle part of Africa, extending north and weft, (Pliny); between the Mediterranean to the north, and Ethiopia to the eaft; and was two-fold, the *Hiiber* or *Exterior Libya*; and the *Farther* or *Interior*. The former lay between the Mediterranean on the north, and the *Farther Libya* and Ethiopia beyond Egypt on the fouth, (Ptolemy). The *Farther* or *Interior Libya*, was a vaft country, lying between the *Hiiber Libya* on the north, the Atlantic ocean on the weft, the Ethiopic on the fouth, and Ethiopia beyond Egypt on the eaft, (Ptolemy).

LIBYA, in a ftill more reftained fenfe, called, for diftinction's fake, *Libya Propria*, was a northern diftrict of Africa, and a part of the *Hiiber Libya*; fited between Egypt to the eaft, the Mediterranean to the north, the Syrtis Major and the Regio Tripolitana to the weft, the Garamantes and Ethiopia beyond Egypt to the fouth. Now the kingdom and defart of *Barca*. This Libya was again fubdivided into *Libya* taken in the ftrictelt fenfe of all, and into Marmarica and Cyrenaica. *Libya* in the ftrictelt fenfe, otherwife the *Exterior*, was the moft eaftern part of *Libya Propria*, next to Egypt, with Marmarica on the weft, the

Mediterranean on the north, and the Nubi, now called *Nubia*, to the south, (Ptolemy).

LICENCE, in law, an authority given to a person to do some lawful act.

LICENSER of the *Press*. See *LIBERTY of the Press*.

LICENTIATE, one who has obtained the degree of a licence.—The greatest number of the officers of justice in Spain are distinguished by no other title than that of *licentiate*. In order to pass *licentiate* in common law, civil law, and physic, they must have studied seven years, and in divinity ten. Among us a *licentiate* usually means a physician who has a licence to practise, granted by the college of physicians.

LICETUS, a celebrated physician of Italy, was born at Rappollo, in the state of Genoa, 1577. He came, it seems, into the world, before his mother had completed the seventh month of her pregnancy; but his father, being an ingenious physician, wrapped him up in cotton, and nurtured him so, that he lived to be 77 years of age. He was trained with great care, and became a very distinguished man in his profession; and was the author of a great number of works: his book *De Morbis* every body must have heard of. He was professor of philosophy and physic at Padua, where he died in 1655.

LICHEN, LIVER WORT, in botany; a genus of the natural order of algae, belonging to the cryptogamia class of plants. The male receptacle is roundish, somewhat plain and shining. In the female the leaves have a farina or mealy substance scattered over them. There are about 130 species, all found in Britain. Among the most remarkable are the following:

1. The *geographicus*; it is frequent in rocks, and may be readily distinguished at a distance. The crust or ground is of a bright greenish-yellow colour, sprinkled with numerous plain black tubercles; which frequently run into one another, and form lines resembling the rivers in a map, from which last circumstance it takes its name.

2. The *calcareus*, or black-nobbed dyer's lichen, is frequent on calcareous rocks; and hath a hard, smooth, white, stoney, or tartareous crust, cracked or tessellated on the surface, with black tubercles. Dillenius relates, that this species is used in dyeing, in the same manner as the *tartareus* after mentioned.

3. The *ventosus*, or red spangled tartareous lichen, hath a hard tartareous crust, cracked and tessellated on the surface, of a pale yellow colour when fresh, and a light olive when dry. The tubercles are of a blood-red colour at top, their margin and base of the same colour as the crust. The texture and appearance of this (according to Mr Lightfoot), indicate that it would answer the purposes of dyeing as well as some others of this tribe, if proper experiments were made.

4. The *candelarius*, or yellow farinaceous lichen, is common upon walls, rocks, boards, and old pales. There are two varieties. The first has a farinaceous crust of no regular figure, covered with numerous, small, greenish-yellow, or olive shields, and grows commonly upon old boards. The other has a smooth, hard, circular crust, wrinkled and lobed at the circumference, which adheres closely to rocks and stones. In the centre are numerous shields of a deeper yellow or orange colour, which, as they grow old, swell in the middle, and assume the figure of tubercles. The inhabitants of Smaland in Sweden scrape this lichen from

the rocks, and mix it with their tallow, to make golden candles to burn on festival days.

5. The *tartarius*, or large yellow-faucer'd dyer's lichen, is frequent on rocks, both in the Highlands and Lowlands of Scotland. The crust is thick and tough, either white, or greenish-white, and has a rough warted surface. The shields are yellow or buff-coloured, of various sizes, from that of a pin's head to the diameter of a silver penny. Their margins are of the same colour as the crust. This lichen is much used by the Highlanders for dyeing a fine claret or pompadour colour. For this purpose, after scraping it from the rocks, and cleaning it, they steep it in urine for a quarter of a year. Then taking it out, they make it into cakes, and hang them up in bags to dry. These cakes are afterwards pulverised, and the powder is used to impart the colour with an addition of alum.

6. The *parellus*, or crawfish-eye lichen, grows upon walls and rocks, but is not very common. The crusts spread closely upon the place where they grow, and cover them to a considerable extent. They are rough, tartareous, and ash-coloured, of a tough coriaceous substance. The shields are numerous and crowded, having white or ash-coloured, shallow, plain discs, with obtuse margins. This is used by the French for dyeing a red colour.

7. The *saxatilis*, or grey-blue pitted lichen, is very common upon trunks of trees, rocks, tiles, and old wood. It forms a circle two or three inches diameter. The upper surface is of a blue-grey and sometimes of a whitish ash-colour, uneven, and full of numerous small pits or cavities; the under side is black, and covered all over, even to the edges, with short simple hairs or radicles. A variety sometimes occurs with leaves tinged of a red or purple colour. This is used by finches and other small birds in constructing the outside of their curiously formed nests.

8. The *omphalodes*, or dark-coloured dyers lichen, is frequent upon rocks. It forms a thick widely-expanded crust of no regular figure, composed of numerous imbricated leaves of a brown or dark-purple colour, divided into small segments. The margins of the shields are a little crisped and turned inwards, and their outside ash-coloured. The lichen is much used by the Highlanders in dyeing a reddish brown colour. They steep it in urine for a considerable time, till it becomes soft and like a paste; then, forming the paste into cakes, they dry them in the sun, and preserve them for use in the manner already related of the *tartarius*.

9. The *parietinus*, or common yellow wall-lichen, is very common upon walls, rocks, tiles of houses, and trunks of trees. It generally spreads itself in circles of two or three inches diameter, and is said to dye a good yellow or orange colour with alum.

10. The *islandicus*, or eatable Iceland lichen, grows on many mountains both of the Highlands and Lowlands of Scotland. It consists of nearly erect leaves about two inches high, of a stiff substance when dry, but soft and pliant when moist, variously divided without order into broad distant segments, bifid or trifid at the extremities. The upper or interior surface of the leaves is concave, chequered colour, smooth, and shining, but red at the base; the under or exterior surface is smooth and whitish, a little pitted, and sprinkled with very minute black warts. The margins of the leaves and all the segments from bottom to top are ciliated with small,

Lichen.

short, stiff, hair-like spinules, of a dark chestnut colour, turning towards the upper side. The shields are very rarely produced. For the uses of this as an esculent herb, see ICELAND, n° 10. Made into broth or gruel, it is said to be very serviceable in coughs and consumptions; and, according to Haller and Scopoli, is much used in these complaints in Vienna.

11. The pulmonarius, or lung-wort lichen, grows in shady woods upon the trunks of old trees. The leaves are as broad as a man's hand, of a kind of leather-like substance, hanging loose from the trunk on which it grows, and laciniated into wide angular segments. Their natural colour, when fresh, is green; but in drying, they turn first to a glaucous and afterwards to a fuscous colour. It has an astringent, bitter taste; and, according to Gmelin, is boiled in ale in Siberia, instead of hops. The ancients used it in coughs and asthma, &c. but it is not used in modern practice.

12. The calicaris, or beaked lichen, grows sometimes upon trees, but more frequently upon rocks, especially on the sea-coasts, but is not very common. It is smooth, glossy, and whitish, producing flat or convex shields, of the same colour as the leaves, very near the summits of the segments, which are acute and rigid, and, being often reflected from the perpendicular by the growth of the shields, appear from under their limbs like a hooked beak. This will dye a red colour; and promises, in that intention, to rival the famous *Lichen Rocella* or *Argol*, which is brought from the Canary Islands, and sometimes sold at the price of 80 l. per ton. It was formerly used instead of starch to make hair-powder.

13. The prunastri, or common ragged hoary lichen, grows upon all sorts of trees; but it is generally moist white and hoary on the sloe and old palm trees, or upon old pines. This is the most variable of the whole tribe of lichens, appearing different in figure, magnitude, and colour, according to its age, place of growth, and sex. The young plants are of a glaucous colour, slightly divided into small acute crested segments. As they grow older, they are divided like a stag's horn, into more and deeper segments, somewhat broad, flat, soft, and pitted on both sides, the upper surface of a glaucous colour, the under one white and hoary.—The male plants, as Linnæus terms them, are short, seldom more than an inch high, not hoary on the under side; and have pale glaucous shields situated at the extremities of the segments, standing on short peduncles, which are only small stiff portions of the leaf produced.—The female specimens have numerous farinaceous tubercles both on the edges of their leaves, and the wrinkles of their surface.—The pulverised leaves have been used as a powder for the hair, and also in dyeing yarn of a red colour.

14. The juniperinus, or common yellow tree-lichen, is common upon the trunks and branches of elms and many other trees. Linnæus says it is very common upon the juniper. The Gothland Swedes dye their yarn of a yellow colour with it, and give it as a specific in the jaundice.

15. The caninus, or ash-coloured ground-liverwort, grows upon the ground among moss, at the roots of trees in shady woods, and is frequent also in heaths and stony places. The leaves are large, gradually dilated towards the extremities, and divided into roundish elevated lobes. Their upper side, in dry weather, is ash-

coloured; in rainy weather, of a dull fuscous green colour; their under-side white and hoary, having many thick downy nerves, from which descend numerous, long, white, pencil-like radicles. The peltæ, or shields, grow at the extremities of the elevated lobes, shaped like the human nail; of a roundish oval form, convex above, and concave beneath; of a chocolate colour on the upper side, and the same colour with the leaves on the under. There are two varieties, the one called *reddish*, and the other *many-fingered*, ground-liverwort. The former is more common than the other. This species has been rendered famous by the celebrated Dr Mead, who asserted that it was an infallible preventative of the dreadful consequences attending the bite of a mad dog. He directed half an ounce of the leaves dried, and pulverised to be mixed with two drachms of powdered black pepper. This was to be divided into four doses, one of which was to be taken by the patient every morning fasting, for four mornings successively, in half a pint of warm cow's milk; after which he was to use the cold bath every morning for a month. It is much to be lamented, however, that the success of this medicine, or indeed any other recommended for the same purpose, hath not always answered the expectation. There are instances where the application has not prevented the hydrophobia, and it is even uncertain whether it has ever been instrumental in keeping off that disorder.

16. The apothosus, or green ground-liverwort with black warts, grows upon the ground at the roots of trees in woods, and other stony and mossy places. It differs very little from the foregoing, and according to some is only a variety of it. Linnæus informs us, that the country-people of Upland in Sweden give an infusion of this lichen in milk to children that are troubled with the disorder called the *thrush* or *apthæ*, which induced that ingenious naturalist to bestow upon it the trivial name of *apthosus*. The same writer also tells us, that a decoction of it in water purges upwards and downwards, and will destroy worms.

17. The cocciferus, or scarlet-tipped cup-lichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small laciniated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth; but may be in general readily distinguished by its frutifications, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the stalk. These tubercles, steeped in an alkaline lixivium, are said to dye a fine durable red colour.

18. The rangiferinus, or rein-deer lichen, is frequent in woods, heaths, and mountainous places. Its general height, when full grown, is about two inches. The stalk is hollow, and very much branched from bottom to top: the branches are divided and subdivided, and at last terminated by two, three, four, or five very fine, short, nodding horns. The axillæ of the branches are often perforated. The whole plant is of a hoary white or grey colour, covered with white farinaceous particles, light and brittle when dry, soft and elastic when moist. The frutifications are very minute, round, fuscous, or reddish-brown tubercles, which grow on the very extremities of the finest branches; but these

Lichen
||
Lichten-
fels.

Lichten-
stein
||
Liddel.

tubercles are very seldom found. The plant seems to have no foliaceous ground for the base, nor scarcely any visible roots.—Linneus tells us, that in Lapland this moss grows so luxuriant that it is sometimes found a foot high. There are many varieties of this species, of which the principal is the *sylvaticus*, or brown-tipt rein-deer lichen. The most remarkable difference between them is, that the *sylvaticus* turns fulvous by age, while the other always continues white. For the uses of these species, see LAPLAND.

19. The *plicatus*, or official stringy lichen, grows on the branches of old trees, but is not very common. The stalks are a foot or more in length, cylindrical, rigid, and, string-shaped, very irregularly branched, the branches entangled together, of a cinereous or ash-colour, brittle and stringy if doubled short, otherwise tough and pliant, and hang pendent from the trees on which they grow. The shields grow generally at the extremities of the branches, are nearly flat, or slightly concave, thin, ash-coloured above, pale-brown underneath, and radiated with fine rigid fibres. As the plant grows old, the branches become covered with a white, rough, warty crust; but the young ones are destitute of it. It was formerly used in the shops as an astringent to stop hæmorrhages, and to cure ruptures; but is out of the modern practice. Linneus informs us, that the Laplanders apply it to their feet to relieve the excoriations occasioned by much walking.

20. The *barbatus*, or bearded lichen, grows upon the branches of old trees in thick woods and pine-forests. The stalks or strings are slightly branched and pendulous, from half a foot to two feet in length, little bigger than a tailor's common sewing thread; cylindrically jointed towards the base; but surrounded every where else with numerous, horizontal, capillary fibres, either simple or slightly branched. Their colour is a whitish green. This has an astringent quality like the preceding. When steeped in water, it acquires an orange colour; and, according to Dillenius, is used in Pennsylvania for dyeing that colour.

21. The *vulpinus*, or gold-wiry lichen, grows upon the trunks of old trees, but is not very common. It is produced in erect tufts, from half an inch to two inches in height, of a fine yellow or lemon-colour, which readily discovers it. The filaments which compose it are not cylindrical, but a little compressed and uneven in the surface, variously branched, the angles obtuse, and the branches straggling and entangled one with another. Linneus informs us, that the inhabitants of Smaland in Sweden dye their yarn of a yellow colour with this lichen; and that the Norwegians destroy wolves by stuffing dead carcases with this moss reduced to powder, and mixed with pounded glass, and so exposing them in the winter-season to be devoured by those animals.

LICHFIELD. See LITCHFIELD.

LICHTENBERG, a castle of France, in Lower Alsace, and the chief place of a county of the same name; seated on a rock, near the mountains Volges, and is looked upon as impregnable. E. Long. 7. 35. N. Lat. 48. 55.

LICHTENBURG, a town of Germany, in the circle of Franconia, and margravate of Culmbach. E. Long. 12. 0. N. Lat. 50. 26.

LICHTENFELS, a town of Germany, in the

circle of Franconia, and bishopric of Bamberg, seated on the river Mayne, in E. Long. 11. 10. N. Lat. 50. 20.

LICHTENSTEIN, a town of Switzerland, in Tockenberg, seated on the river Thour. E. Long. 2. 15. N. Lat. 47. 25.

LICHTSTALL, an handsome town of Switzerland, in the county of Basle; seated on the river Ergetz. In E. Long. 7. 57. N. Lat. 47. 40.

LICINIUS STOLO, a famous Roman tribune, styled *Stolo* on account of a law he made, while tribune, that no Roman citizen should possess more than 500 acres of land; alleging, that when they occupied more, they could not cultivate it with care, nor pull up the useless shoots (*folones*) that grow from the roots of trees. He is memorable also for enacting, that one of the consuls should always be of a Plebeian family. He lived about 362 B. C.

LICNON, in the Dionysian solemnities, the mystical van of Bacchus; a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it. See DIONYSIA.

LICNOPHORI, in the Dionysian solemnity, those who carried the licnon.

LICOLA, or LAGO-DI-LICOLA, a lake in the kingdom of Naples, formerly famous for plenty of excellent fish; but in the year 1538 an explosion of a volcano changed one part of it into a mountain of ashes, and the other into a morass. It was anciently known by the name of the Lucrine-lake.

LICONIA, in botany: A genus of the digynia order, belonging to the pentandria class of plants. There are five petals inlaid in the pit of the nectarium at its base; the capsule is bilocular and seed-bearing.

LICTORS, among the Romans, were officers established by Romulus, who always attended the chief magistrates when they appeared in public.

The duty of their office consisted in the three following particulars: 1. *Submotio*, or clearing the way for the magistrate they attended: this they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. *Animadversio*, or causing the people to pay the usual respect to the magistrate, as to alight, if on horseback or in a chariot; to rise up, uncover, make way, and the like. 3. *Præatio*, or walking before the magistrates: this they did not confusedly, or altogether, nor by two or three abreast, but singly following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was also part of their office to arrest criminals, and to be public executioners in beheading, &c. Their ensigns were the *FASCES* and *SECURIS*.

As to the number of lictors allowed each magistrate, a dictator had twenty-four, a master of the horse six, a consul twelve, a prætor six; and each vestal virgin, when she appeared abroad, had one.

LIDD. See LYDD.

LIDDEL (Dr Duncan), professor of mathematics and of medicine in the university of Helmstadt, was born in the year 1561 at Aberdeen, where he received the first part of his education in languages and philosophy. About the age of eighteen he repaired to the university of France, where he spent three years in a diligent application to mathematics and philosophy. From France he proceeded to Wratisslaw, or Breslaw, in Silesia, where

he is said to have made uncommon progress in his favourite study of mathematics, under the direction of a very eminent professor, Paulus Wittichius. Having studied at Breslaw for the space of one year, he returned to Francfort, and remained there three years, paying the most intense application to the study of physic. A contagious distemper having broke out at that place, the students were dispersed, and Liddel retired to the university of Rostock. Here he renewed his studies, rather as a companion than as a pupil of the celebrated Bruceus, who, though an excellent mathematician, did not scruple to confess that he was instructed by Liddel in the more perfect knowledge of the Copernican system, and other astronomical questions. In 1590 he returned once more to Francfort. But having there heard of the increasing reputation of the Academia Julia, established at Helmstadt by Henry duke of Brunswick, Mr Liddel removed thither; and soon after his arrival was appointed to the first or lower professorship of mathematics. From thence he was promoted to the second and more dignified mathematical chair, which he occupied for nine years, with much credit to himself and to the Julian Academy. In 1596 he obtained the degree of M. D. was admitted a member of that faculty, and began publicly to teach physic. By his teaching and his writings he was the chief support of the medical school at Helmstadt; was employed as first physician at the court of Brunswick, and had much practice among the principal inhabitants of that country. Having been several times elected dean of the faculties both of philosophy and physic, he had in the year 1604 the honour of being chosen professor of the university. But neither academical honours, nor the profits of an extensive practice abroad, could make Dr Liddel forget his native country. In the year 1600 he took a final leave of the Academia Julia; and after travelling for some time through Germany and Italy, he at length settled in Scotland. He died in the year 1613, in the fifty-second year of his age. By his last will he bestowed certain lands purchased by him near Aberdeen upon the university there, in all time coming, for the education and support of six poor scholars. Among a variety of regulations and injunctions for the management of this charity, he appoints the magistrates of Aberdeen his trustees, and solemnly denounces the curse of God on any person who shall abuse or misapply it. His works are, 1. *Disputationes Medicinales, Helmstadt, 1603, 4to.* 2. *Arts Medicae succincte et perspicue explicatae, Hamburgi, 1607, 8vo.* This performance is dedicated to king James VI. and is divided into five books, viz. *Introductio in totam Medicinam; De Physiologia; De Pathologia; De Signorum doctrina; De Therapeutica.* 3. *De Febrilibus Libri tres, Hamburgi, 1610, 12mo.* 4. *Tractatus de dentibus aureis, Hamburgi, 1628, 12mo.* This last performance Dr Liddel published in order to refute a ridiculous story then current of a poor boy in Silesia, who, at seven years of age, having lost some of his teeth, brought forth, to the astonishment of his parents, a new tooth of pure gold. Jacobus Horstius, doctor and professor of medicine in the Academia Julia, at the same time with our author, had published a book, which he dedicated to the Emperor Rudolphus II. to prove that this wonderful tooth was a prodigy sent from heaven to encourage the Germans then at war with the Turks, and foretelling, from this golden tooth, the future victories of the Christians, with the final destruction of the Turkish empire

and Mahometan faith, and a return of the golden age in 1700, preparatory to the end of the world. The imposture was soon after discovered to be a thin plate of gold, skilfully drawn over the natural tooth by an artist of that country, with a view to excite the public admiration and charity. 5. *Artis conferendi Sanitatem, libri duo, Aberdonie, 1651, 12mo.*; a posthumous work. The merit of these works of Dr Liddel, it is not now necessary to estimate with precision. They appear, however, to contain the most fashionable opinions and practice, in the medical art, of the age in which he lived; nor is there almost any disease or medical subject then known of which he has not treated in one or other of his writings. Of his language it may be sufficient to observe, that the Latin is at least as pure as is generally found among medical writers, and that his style is plain and perspicuous, and sometimes even elegant.

LIDFORD, a village of Devonshire in England, situated on the river Lid, two or three miles east of Brent Tor, was formerly a famous town, with a castle, which was always committed to men of quality, and twice sent burgesses to parliament. It was sadly shattered by the Danes in 997: and though now a contemptible village, the parish may for lands and liberties compare with any in the kingdom, the whole forest of Dartmore being in the verge of it. The river here being pent up at the bridge with rocks, has made itself so deep a fall, by its continual working, that passengers only hear the noise of the water without seeing it.

LIDKOPING, a town of West Gothland in Sweden, seated on the lake Wenar, in E. Long. 13. 40. N. Lat. 58. 25.

LIDNEY, a town of Gloucestershire in England, 71 miles from London, is seated on the west bank of the river Severn, and has a market on Wednesdays, with two fairs in the year. In the neighbourhood are the remains of a large Roman encampment, with foundations of many ancient buildings, among which are the ruins of a Roman hypocaust of an oval form, and Roman antiquities and coins are often found here in great number. Mr Bathurst has a fine seat here called *Sydney-Park*, with very extensive woods adjoining.

LIE, in morals, denotes a criminal breach of veracity. — Archdeacon Paley, in treating of this subject, observes, that there are falsehoods which are not lies; that is, which are not criminal: and there are lies which are not literally and directly false.

I. Cases of the first class are those, 1. Where no one is deceived: as for instance in parables, fables, novels, jests, tales to create mirth, or ludicrous embellishments of a story, in which the declared design of the speaker is not to inform, but to divert; compliments in the subscription of a letter; a prisoner's pleading not guilty; an advocate asserting the justice, or his belief of the justice, of his client's cause. In such instances no confidence is destroyed, because none was reposed; no promise to speak the truth is violated, because none was given or understood to be given. 2. Where the person you speak to has no right to know the truth, or more properly where little or no inconvenience results from the want of confidence in such cases; as where you tell a falsehood to a madman for his own advantage; to a robber to conceal your property; to an assassin to defeat or to divert him from his purpose. It is upon this principle, that, by the laws of war, it is allowed to deceive an enemy by feints, false colours,

Lie
||
Li gr.

Liege.

spies, false intelligence, and the like: but, by no means, in treaties, truces, signals of capitulation, or surrender: and the difference is, that the former supposes hostilities to continue, the latter are calculated to terminate or suspend them.

Many people indulge in serious discourse a habit of fiction and exaggeration, in the accounts they give of themselves, of their acquaintance, or of the extraordinary things which they have seen or heard; and so long as the facts they relate are indifferent, and their narratives though false are inoffensive, it may seem a superstitious regard to truth to censure them merely for truth's sake. Yet the practice ought to be checked: for, in the first place, it is almost impossible to pronounce beforehand, with certainty, concerning any lie, that it is inoffensive; or to say what ill consequences may result from a lie apparently inoffensive: And, in the next place, the habit, when once formed, is easily extended to serve the designs of malice or interest; like all habits, it spreads indeed of itself. Pious frauds, as they are improperly enough called, pretend inspirations, forged books, counterfeit miracles, are impositions of a more serious nature. It is possible that they may sometimes, though seldom, have been set up and encouraged with a design to do good: but the good they aim at requires, that the belief of them should be perpetual, which is hardly possible; and the detection of the fraud is sure to disparage the credit of all pretensions of the same nature. Christianity has suffered more injury from this cause than from all other causes put together.

II. As there may be falsehoods which are not lies, so there may be lies without literal or direct falsehood. An opening is always left for this species of prevarication, when the literal and grammatical signification of a sentence is different from the popular and customary meaning. It is the wilful deceit that makes the lie; and we wilfully deceive, when our expressions are not true, in the sense in which we believe the hearer apprehends them. Besides, it is absurd to contend for any sense of words, in opposition to usage; for all senses of all words are founded upon usage, and upon nothing else. Or a man may act a lie; as by pointing his finger in a wrong direction, when a traveller inquires of him his road; or when a tradesman shuts up his windows, to induce his creditors to believe that he is abroad: for to all moral purposes, and therefore as to veracity, speech and action are the same; speech being only a mode of action.

LIECHTENAU, a town of Germany, in the circle of Franconia and margravate of Anspach, subject to Nuremberg. E. Long. 9. 5. N. Lat. 48. 43.

LIEGE (*Ligius*), in law, properly signifies a vassal, who holds a kind of fee, that binds him in a closer obligation to his lord than other people.

The term seems to be derived from the French *lier* "to bind;" on account of a ceremony used in rendering faith or homage; which was by locking the vassal's thumb or his hand in that of the lord, to show that he was fast bound by his oath of fidelity. Cujas, Vigenere, and Bignon, choose rather to derive the word from the same source with *leudis* or *leodi*, "loyal, faithful." But Du Cange falls in with the opinion of those who derive it from *liti*, a kind of vassals, so firmly attached to their lord, on account of lands or

fees held of him, that they were obliged to do him all manner of service, as if they were his domestics. He adds, this was formerly called *litium servitium*, and the person *lige*. In this sense, the word is used, Leg. Edw. cap. 29. *Judei sub tutela regis ligea debent esse*; that is, wholly under his protection.

By liege homage, the vassal was obliged to serve his lord towards all, and against all, excepting his father. In which sense, the word was used in opposition to simple homage; which last only obliged the vassal to pay the rights and accustomed dues to his lord; and not to bear arms against the emperor, prince, or other superior lord: so that a liege man was a person wholly devoted to his lord, and entirely under his command. *Omnibus, &c. Reginaldus, rex Insularum, salutem. Sciatis quod deveni homo ligeus domini regis Anglie Johannis, contra omnes mortales, quamdiu visco; & inde ei fidelitatem & sacramentum prestavi, &c.* MS. penes W. Dugdale.

But it must be observed, there were formerly two kinds of liege homage: the one, by which the vassal was obliged to serve his lord, against all, without exception even of his sovereign; the other, by which he was to serve him against all, except such other lords as he had formerly owed liege homage to.

In our old statutes lieges, and liege people, are terms peculiarly appropriated to the king's subjects; as being *liges*, *ligi*, or *ligati*, obliged to pay allegiance to him; 8 Henry VI. 14 Hen. VIII. &c. though private persons had their lieges too. *Reinaldus, Dei gratia, abbas Ramseie, presbiter & hominibus de Brancestre, & omnibus vicinis Francis & Anglis, salutem. Sciatis me dedisse terram Ulst, in depedene (hodie depedate) huic Boselino, & uxori ejus Alstine—ea condicione quod effecti sint homines liberi.* Lib. Ramef.

LIEGE-Pouffe, in Scots law, is opposed to deathbed; and signifies a person's enjoying that state of health in which only he can dispose of his property at pleasure.

LIEGE, a bishopric of Germany, in the circle of Westphalia; bounded to the north by Brabant, to the south by Champagne and Luxemburg, to the east by Limburg and Juliers, and to the west by Brabant, Namur, and Hainault. It is very unequal both in length and breadth; the former being in some places above 90 miles, in others not half so much; and the latter in some places 45, in others hardly 25. The air here is very temperate; and the soil fruitful in corn, wine, wood, and pasture. Here also are mines of lead and iron, pits of coal, quarries of marble and stone, and some celebrated mineral waters, as those of Spa and Chau-fontaine. The principal rivers are, the Maes and Sambre. The manufactures and commodities of the country are chiefly beer, arms, nails, serge, leather, with the products we have just mentioned. The states of the bishopric are composed of three bodies: the first is the chapter of Liege; the second, the nobility of the country; and the third, the deputies of the capital and the other towns. The three estates are seldom called together, except to raise taxes for the service of the province, or upon some particular emergency; but there is a committee of the states, who meet thrice a-week, and in time of war daily. They are always about the prince-bishop, to make remonstrances, and demand the redress of grievances. The bishop is spiritual and temporal lord

of.

Liege.

of the whole country; but, as bishop, is suffragan to the archbishop of Cologne. He styles himself, *by the grace of God, bishop and prince of Liege, duke of Bouillon, marquis of Franchimont, count of Loos, Hoorn, &c.* His arms for Liege are, a pillar argent, on a pedestal of the same, with a crown or, in a field ruby. In the matricula he was formerly rated at 50 horse and 170 foot; or 1280 florins monthly, in lieu of them, but now only at 826. An abatement of one third has also been granted of the ancient assisement to the chamber-court, which was 360 rix-dollars 62½ knitzers for each term. Here are several colleges which sit at Liege, for the government of the country, and the decision of causes, civil, criminal, spiritual, and feudal, and of such also as relate to the finances. The chapter consists of 60 persons, who must either prove their nobility for four generations, both by father and mother, before they can be admitted: or if they cannot do that, must at least have been doctors or licentiates of divinity for seven years, or, of law, for five years, in some famous university. The bishopric is very populous and extensive, containing 1500 parishes, in which are 24 walled towns, besides others, 52 baronies, besides counties and seigniories, 17 abbeys for men, who must be all gentlemen, and 11 for ladies, exclusive of others.

LIEGE, the capital of the bishopric of the same name, stands upon the Maes, in a fine valley, surrounded with woods and hills, being a free imperial city, and one of the largest and most eminent in Europe. Though it is 100 miles from the sea by water, the Maes is navigable up to it. The city has 16 gates; 17 bridges, some of them very handsome; 154 streets, many of them straight and broad; a fine episcopal palace; a very large stately cathedral, in which, besides five great silver coffers full of reliques, are several silver statues of saints, and a St George on horseback of massy gold, presented to the cathedral by Charles the Bold, by way of atonement for using the inhabitants cruelly in the year 1468. Of the other churches, that of St Paul is the most remarkable, both for its structure and fine ornaments in painting and marble. The city is well fortified, and there are also two castles on the mountain of the Holy Walburg for its defence. Besides a great number of other convents of both sexes, here is a college of English Jesuits, founded in the year 1616, and a fine nursery of English ladies. Indeed, churches, convents, and other religious foundations, take up the greater part of it. The reader, therefore, no doubt, will take it for granted, that it is a most blessed, holy, and happy city. But however it may fare with the profane, unhallowed laity, it is certainly the paradise of priests, as it is expressly called, by way of eminence. It is divided into the old and new, or the upper and lower; and the latter again into the island, and the quarter beyond the Maes. The houses are high, and built of bluish marble. In the town and suburbs are 12 public places or squares, 10 hospitals, a beguin-house, and two fine keys, planted with several rows of trees, for the burghers to take the air; but a great part of that within the walls is taken up with orchards and vineyards. The manufactures of this city are arms, nails, leather, serge, and beer. In St William's convent, without the city, is the tomb of the famous

Liege.

English traveller Sir John Mandeville, with an inscription in barbarous French, requesting those who read it to pray for his soul. Near it are kept the fiddle, spurs, and knife, that he made use of in his travels. After having seen most of the cities of any note in the world, he made choice of this to spend the eve of his life in. A little way from the city, on the other side the Maes, stands the episcopal palace of Seraing, in which the bishops generally reside during the summer. The latitude of this city is 50. 36. N. and the longitude 5. 40. E.

Some disturbances took place here in the year 1789, in consequence of certain disputes that had arisen between the prince-bishop and the inhabitants. The latter having demanded certain privileges, which he did not think proper to grant, they took up arms, and compelled him and his chapter to comply with their request. The prince, together with many of the clergy, nobility, and citizens, alarmed by this commotion, and dreading the consequences of popular fury, which when once roused, seldom knows any bounds, sought safety by a voluntary exile. They then appealed to the imperial chamber; and this tribunal, instead of acting the part of arbiter, decided as a sovereign, and ordered the circles of the Lower Rhine and Westphalia to execute the sentence.

The king of Prussia, at whose court one of the chiefs of the insurrection had resided, and who wished to gain a party at Liege, became mediator; and seemed to favour the Liegeois, many of whose claims were just, though they attempted to enforce them by violence and the most illegal steps. Intoxicated with this protection, the people of Liege treated the remonstrances of their bishop, the decrees of the imperial chamber, and the resolutions of the directory of the two circles, with the utmost contempt; and proceeded so far as even to dethrone their prince, by appointing a regent in the person of a French prelate. The electoral college having deliberated on the best means of putting an end to these disturbances, its propositions, though modified by M. Dolm the Prussian plenipotentiary, made the insurgents break out into open sedition. Deluded by their leaders, they gave themselves up every day to new excesses; the effects of the citizens were exposed to pillage, and their persons to insult. The king of Prussia, who was desirous to bring matters to an accommodation, and not to instigate the Liegeois to become independent, finding that the efforts of his minister were not attended with the desired success, seemed unwilling to interfere any farther in an affair which might have led him into a quarrel with the empire. The executive troops, at the same time, remained almost in a state of inactivity; and seemed rather to guard the frontiers of this petty state, than to make any attempt to reduce it to obedience. Neither this conduct, however, nor the exhortations of Prussia, added to the moral certainty of their being soon compelled to lay down their arms, made any change in the conduct of the malecontents. They declared openly, in the face of all Europe, that they would either conquer or die; and they persisted in this resolution, while commerce, manufactures, and the public revenues, were going daily to decay.

Having at length openly attacked the executive forces without the territories of their city, the emperor could no longer remain an indifferent spectator. He

Liege,
Lievens.

was now full time to put a period to that madness to which the people had abandoned themselves; and to accomplish this in an effectual manner, the imperial chamber at Wetzlar requested the emperor, as a member of the ancient circle of Burgundy, to execute its orders respecting this object. In consequence of this measure, Baron Alvinzi, who commanded a body of Austrians cantoned in Limburgh and the confines of Brabant, notified, by order of Marshal Bender, to the states and municipality of Liege, that the emperor intended to send troops into their city and territories, for the purpose of restoring tranquillity and good order. The states had already been informed of this resolution by their agent at Wetzlar. They therefore wrote to Marshal Bender, to assure him of the respectful confidence which they placed in the justice and magnanimity of the emperor, and to request that the Austrian troops might enter alone, without those of the electors; and that they might be confined to occupy the gates and the suburbs only. To this letter, which was carried to Brussels by a deputation of the states, Marshal Bender returned a very satisfactory answer, relating to the disposition of the electoral troops: but Baron Alvinzi, in a note which he wrote to the states, insisted among other articles, that all the citizens should throw down their arms; that proper accommodations should be prepared for the officers and men; that the warlike stores, collected for making resistance, should be removed; and that cockades, and every other distinctive mark of the like kind, should be laid aside before the arrival of the Imperial troops. However humiliating these preliminaries might be, especially that of a general disarming, the states and municipalities acquiesced without the least reserve; and their submission, as sudden as complete, was communicated to the people, with an exhortation to follow their example.

Notwithstanding this pacific appearance, two days before the entrance of the Imperial troops, the municipal council of Liege, flattering themselves, perhaps, with the hopes of assistance from Prussia, assured the inhabitants that they would remain unshaken in their post, and that they had sworn never to desert the cause in which they were engaged. This, however, did not prevent the Austrian troops, to the number of 6000, from penetrating, without opposition, into the heart of the city; where they occupied every post; made the citizens lay aside their arms, uniforms, and cockades; and, in a single hour, dethroned so many sovereigns of a year. The greater part of the municipal officers, who, two days before, had solemnly promised such great things, betook themselves to flight, and retired either to France or Wesel; while the ancient magistracy, which had been expelled in the month of August 1789, was provisionally re-instated by the directorial commissioners.—The decrees of the imperial chamber at Wetzlar have since been executed in their utmost extent. The ancient magistracy and the privy-council of the prince bishop have been restored; and the prince himself having returned, peace and good order have been re-established.

LIENTERY, a flux of the belly, in which the aliments are discharged as they are swallowed, or very little altered either in colour or substance. See (*Index* subjoined to) **MEDICINE**.

LIEVENS (John or Jan), a celebrated painter, was Vol. X. Part I.

Lieou-
Kieou.

born at Leyden in 1607. He discovered an early inclination for the arts, and was the disciple first of Joris van Schooten, and afterwards of Peter Lastman. He excelled principally in painting portraits; but he also executed several historical subjects with great success. He came over into England, where he resided three years, and painted the portraits of Charles I. the queen, the prince of Wales, and several of the nobility; after which he returned to Antwerp, where he met with full employment for his pencil. We have several etchings by this master, which are performed in a slight, but masterly manner. The chiaro scuro is very skillfully managed in them, so as to produce a most powerful effect. His style of etching bears some resemblance to that of Rembrandt; but it is coarser in general, and less finished.

LIEOU-KIEOU, the name of certain islands of Asia, subject to China; but hitherto little known to geographers, who have been satisfied with marking their existence and latitude in their charts. They, however, form a powerful and extensive empire, the inhabitants of which are civilized, and ought not to be confounded with other savage nations dispersed throughout the islands of Asia. Father Gabil, a Jesuit, has furnished us with some interesting details respecting these islanders, which he extracted from a Chinese relation, published in 1721, at the end of a voyage that was undertaken on the following account. The emperor Kang-hi having resolved, in 1719, to send an ambassador to the king of Lieou-kieou, chose for this purpose one of the great doctors of the empire, named *Supao-Koang*. This learned man departed from China in 1719, and returned to Peking in 1720, where, in the year following, he caused a relation of his voyage to be published in two volumes. It is in the first of these that he gives an accurate and particular description of the isles of Lieou-kieou; and what he relates appears to be worthy of the greater credit, because, being on the spot, he examined, as he himself says, according to the orders of the emperor, whatever he found curious or interesting, respecting the number, situation, and productions of these isles; as also the history, religion, manners, and customs of the people who inhabit them.

These isles, situated between Corea, Formosa, and Japan, are in number 36. The principal and largest is called *Lieou-kieou*; the rest have each a particular denomination. The largest island extends from north to south almost 440 lys, and 120 or 130 from east to west; but on the south side, the extent from east to west is not 100 lys. The south-east part of the island, where the court resides, is called *Cheouli*; and it is there that Kint-ching, the capital city, is situated. The king's palace, which is reckoned to be four leagues in circumference, is built on a neighbouring mountain. It has four gates, which correspond to the four cardinal points; and that which fronts the west forms the grand entry. The view which this palace commands is most extensive and delightful; it reaches as far as the port of Napakiang, at the distance of ten lys, to the city of Kint-ching, and to a great number of other cities, towns, villages, palaces, temples, monasteries, gardens, and pleasure-houses. It stands in longitude 145° 26 east, and in latitude 26° 2' north.

If we believe these islanders, the origin of their empire

Lieou-
Kieou.

pire is lost in the remotest antiquity. They reckon up 25 successive dynasties, the duration of which forms a period of more than 18,000 years. It would be useless to employ a single moment in pointing out the absurdity of these pretensions. It is however certain, that the existence of the country called *Lieou-kieou* was not known in China before the year 605 of the Christian era. It was in the course of that year, that one of the emperors of the dynasty of Soui, having heard of these isles, was desirous of knowing their situation. This prince at first sent some Chinese thither; but their expedition proved fruitless, as the want of interpreters prevented them from acquiring that knowledge which was the object of their voyage. They only brought some of the islanders with them to Sigan-fou, the capital of the province of Chen-si, which was the usual residence of the emperors of the dynasty of Soui. It fortunately happened, that an ambassador of the king of Japan was then at court. This ambassador and his attendants immediately knew the strangers to be natives of *Lieou-kieou*; but they spoke of these isles as of a miserable and wretched country, the inhabitants of which had never been civilized. The emperor of China afterwards learned, that the principal island lay to the east of a city called at present *Fou-tcheou-fou*, which is the capital of the province of Fo-kien; and that, in a passage of five days, one might reach the large island where the king kept his court.

On this information, the emperor Yang-ti sent skillful men, accompanied by interpreters, to summon the prince to do homage to the emperor of China, and to pay him tribute. This proposal was very ill received. The king of *Lieou-kieou* sent back the Chinese, telling them, sternly, that he acknowledged no prince to be his superior. This answer irritated the emperor, who, to obtain revenge, caused a fleet to be immediately equipped in Fo-kien, in which he embarked 10,000 men. This fleet set sail, and arrived in safety at the port of Napa-kiang. The army, in spite of every effort made by the natives, landed on the island; and the king, who had put himself at the head of his troops to oppose the enemy, having fallen in battle, the Chinese pillaged, sacked, and burnt the royal city, made more than 5000 slaves, and returned to China.

The emperors of the dynasty of Tang, those of the short dynasties that followed, and those of the dynasty of Song, although they were fully informed of every thing respecting the *Lieou-kieou* isles, made no attempts to render them tributary. In 1291, Chi-fou, emperor of the dynasty of Yen, was desirous of reviving the pretensions of his predecessors. He fitted out a fleet to subdue these islands; but schemes of conquest had become disagreeable to the Chinese, since the disaster that befel their army in an expedition against Japan. The fleet of Chi-fou went no farther than the isles of Pong-hou, and the western coast of Formosa, from whence, under divers pretences, they returned to the ports of Fo-kien.

It was only in 1372, under the reign of Hong-vou, founder of the dynasty of Ming, that these islands submitted voluntarily to the Chinese government. Hong-vou had sent one of the grandes of his court to T'fay-tou, who was then reigning at *Lieou-kieou*, to inform him of his accession to the throne. The Chinese nobleman had received particular instructions respecting this

Lieou-
Kieou.

commission, and he acquitted himself of it with all the prudence and address of an able minister. In a private audience which he had with T'fay-tou, he exhorted this prince to declare himself a tributary of the empire, and laid before him the advantages he would derive from this step. His reasoning, supported by the power of his natural eloquence, made so much impression on the mind of T'fay-tou, that he embraced the proposal made him, and sent immediately to the emperor to demand the investiture of his states.

Hong-vou received his envoys in a magnificent manner, and loaded them with presents. He solemnly declared T'fay-tou a vassal of the empire; and, after having received his first tribute (which consisted in valuable horses, aromatic wood, sulphur, copper, tin, &c.) he sent to this prince a golden seal, and confirmed the choice he had made of one of his sons for successor. The emperor afterwards sent 36 families, almost all from the province of Fo-kien to *Lieou-kieou*. T'fay-tou received them, assigned them lands near the port of Napa-kiang, and appointed certain revenues for their use, at the same time that Hong-vou made them considerable remittances. These families first introduced into *Lieou-kieou* the learned language of the Chinese, the use of their characters, and the ceremonies practised in China in honour of Confucius. On the other hand, the sons of several of the grandes of the court of T'fay-tou were sent to Nan-king, to study Chinese in the imperial college, where they were treated with distinction, and maintained at the emperor's expences.

The isles of *Lieou-kieou* had neither iron nor porcelain. Hong-vou supplied this want; he caused a great number of utensils of iron and instruments to be made, which he sent thither, together with a quantity of porcelain vessels. Commerce, navigation, and the arts soon began to flourish. These islanders learned to cast bells for their temples, to manufacture paper and the finest stuffs, and to make porcelain, with which they had been supplied before from Japan.

The celebrated revolution which placed the Tartars on the imperial throne of China, produced no change in the conduct of the kings of *Lieou-kieou*. Chang-tché, who was then reigning, sent ambassadors to acknowledge Chun-tchi, and received a seal from him, on which were engraven some Tartar characters. It was then settled, that the king of *Lieou-kieou* should pay his tribute only every two years, and that the number of persons in the train of his envoys should not exceed 150.

The emperor Kang-hi seemed to pay more attention to these isles than any of his predecessors. He caused a superb palace to be erected in honour of Confucius, and a college where he maintained masters to teach the sciences and the Chinese characters. He also instituted examinations for the different degrees of the literati. He ordained, that the king of *Lieou-kieou* should never send in tribute rose-wood, cloves, or any other production which was not really of the growth of the country; but that he should send a fixed quantity of sulphur, copper, tin, shells, and mother of pearl, which is remarkably pretty in these islands. He permitted, that, besides the usual tribute, he might present him horse-furniture, pistol-cases, and other things of the same kind, which these islanders are said to manufacture with great taste and neatness.

Lieuou-
Kieou.

It is more than 900 years since the bonzes of China introduced at Lieou-kieou the worship of Fo, and the principal books belonging to their sect. This worship is at present the established religion both of the grantees and of the people. There is still to be seen in the royal city a magnificent temple, erected in honour of another idol borrowed from the Chinese, named *Tsin-sey*, which signifies *celestial queen or lady*.

These islanders do not make promises or swear before their idols. When they have occasion to do this, they burn perfumes, present fruits, and stand respectfully before some stone, which they call to witness the solemnity of their engagements. Numbers of stones are to be seen in the courts of their temples, in most public places, and upon their mountains, which are entirely appropriated to this purpose. They have also among them women consecrated for the worship of spirits, who are supposed to have great influence over these beings. They visit the sick, distribute medicines, and recite prayers for their recovery.

They respect the dead as much as the Chinese, and they are no less ceremonious in wearing mourning; but their funerals are neither so pompous, nor attended with so much expence. Their coffins, which are of an hexagonal or octagonal figure, are three or four feet high. They burn the flesh of the bodies of their dead, and preserve only the bones. They never offer provisions to them; they are contented with placing lamps round them, and burning perfumes.

Different families are distinguished in Lieou-kieou by surnames, as in China; but a man and a woman of the same surname cannot be united in marriage. The king is not permitted to marry but in the three grand families, which always enjoy the highest offices. There is a fourth, of equal distinction to the three former; but neither the king nor the princes contract any alliances with this family; for it is doubtful, whether it be not sprung from the same stem as the royal line.

A plurality of wives is allowed in these isles. Young men and young women enjoy the liberty of seeing one another, and of conversing together; and their union is always in consequence of their own choice. The women are very reserved; they never use paint, and wear no pendants in their ears; they collect their hair on the top of their heads in the form of a curl, and fix it in that manner by means of long pins made of gold or silver.

Besides the vast domains which the king possesses, he receives the produce of all the sulphur, copper, and tin-mines, and of the salt-pits, together with what arises from taxes. From these revenues he pays the salaries of the mandarins and officers of his court. These salaries are estimated at a certain number of sacks of rice; but under this name is comprehended whatever the king gives in grain, rice, silk, cloth, &c. The whole is valued according to the price of the sacks of rice.

There are here, as in China, nine orders of mandarins, who are distinguished by the colour of their caps, or by their girdles and cushions. The greater part of the titles of these mandarins are hereditary in their families; but there are some which are only bestowed upon merit. In the royal city there are tribunals established for managing the revenue and affairs of the principal island, and of all the others which are dependent

on it. The latter have agents, who reside at court. There are also particular tribunals for civil and criminal matters; for whatever concerns the families of the grantees and princes; for the affairs of religion; for inspecting the public granaries, king's revenues, duties; for commerce, manufactures, civil ceremonies, and for navigation, public edifices, literature, and war.

The vessels that are built in this country are greatly valued by the people of China and Japan. In these the natives go not only from one island to another, but also to China, Tong-king, Cochinchina, Corea, Nangaza-ki, Satsuma, the neighbouring isles, and to Formosa, where they dispose of their different commodities. Besides those articles of commerce which their manufactures of silk, cotton, paper, arms, copper utensils, &c. furnish them, they also export mother of pearl, tortoise and other shells, coral and whet-stones, which are in great request both in China and Japan.

LIEUTAUD (Dr Joseph), counsellor of state and first physician at the court of France, was born at Aix in Provence, and resided principally there till he took the degree of doctor of medicine. After this he prosecuted his studies for some years at Montpellier. He returned to Aix, where he soon acquired extensive practice, and became eminent for literary abilities. He resided there till the year 1750, when he was invited to act as physician to the royal infirmary at Versailles. There he practised with such reputation and success, that he soon arrived at the head of his profession; and in the year 1774, upon the death of M. Senac, he was appointed archiater. His extensive engagements in practice did not prevent him from cultivating the science of medicine in all its branches, and from freely communicating to others the result of his own studies. He published many valuable works; amongst which the following may be accounted the most remarkable. 1. *Elementa Philologiae*. 2. *Precis de la Medecine*. 3. *Pratique Precis de la Matière Medicale*. 4. *Essais Anatomique*. 5. *Synopsis Universæ Praxeos Medicinæ*. 6. *Historia Anatomico-Medicæ*. He died at Versailles in 1780, aged 78 years.

LIEUTENANT, an officer who supplies the place and discharges the office of a superior in his absence. Of these, some are civil, as the lords lieutenants of kingdoms, and the lords-lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-colonel, &c.

Lord LIEUTENANT of Ireland, is properly a viceroy; and has all the state and grandeur of a king of England, except being served upon the knee. He has the power of making war and peace, of bestowing all the offices under the government, of dubbing knights, and of pardoning all crimes except high treason; he also calls and prorogues the parliament, but no bill can pass without the royal assent. He is assisted in his government by a privy-council; and, on his leaving the kingdom, he appoints the lords of the regency, who govern in his absence.

Lord LIEUTENANTS of Counties, are officers, who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lord-lieutenants, are deputy-lieutenants, who have the same power:

Lieutaud,
Lieutenant.

LIEUTENANT—these are chosen by the lords-lieutenants, out of the principal gentlemen of each county, and presented to the king for his approbation.

LIEUTENANT-Colonel. See COLONEL.

LIEUTENANT-General. See GENERAL.

LIEUTENANT, in the land-service, is the second commissioned officer in every company of both foot and horse, and next to the captain, and who takes the command upon the death or absence of the captain.

LIEUTENANT of Artillery. Each company of artillery hath four; 1 first and 3 second lieutenants. The first lieutenant hath the same detail of duty with the captain; because in his absence he commands the company; he is to see that the soldiers are clean and neat; that their clothes, arms, and accoutrements, are in good and serviceable order; and to watch over every thing else which may contribute to their health. He must give attention to their being taught the exercise, see them punctually paid, their messes regularly kept, and to visit them in the hospitals when sick. He must assist at all parades, &c. He ought to understand the doctrine of projectiles and the science of artillery, with the various effects of gun-powder, however managed or directed; to enable him to construct and dispose his batteries to the best advantage; to plant his cannon, mortars, and howitzers, so as to produce the greatest annoyance to an enemy. He is to be well skilled in the attack and defence of fortified places; and to be conversant in arithmetic, mathematics, mechanics, &c.

Second **LIEUTENANT in the Artillery**, is the same as an ensign in an infantry regiment, being the youngest commissioned officer in the company, and must assist the first lieutenant in the detail of the company's duty. His other qualifications should be equal with those of the first lieutenant.

LIEUTENANT of a ship of War, the officer next in rank and power to the captain, in whose absence he is accordingly charged with the command of the ship, as also the execution of whatever orders he may have received from the commander relating to the king's service.

The lieutenant who commands the watch at sea, keeps a list of all the officers and men thereto belonging, in order to muster them when he judges it expedient, and report to the captain the names of those who are absent from their duty. During the night-watch, he occasionally visits the lower decks, or sends thither a careful officer, to see that the proper centinels are at their duty, and that there is no disorder amongst the men; no tobacco smoked between decks, nor any fire or candles burning there, except the lights which are in lanterns, under the care of a proper watch, on particular occasions. He is expected to be always upon deck in his watch, as well to give the necessary orders with regard to trimming the sails and superintending the navigation, as to prevent any noise or confusion; but he is never to change the ship's course without the captain's directions, unless to avoid an immediate danger.

The lieutenant, in time of battle, is particularly to see that all the men are present at their quarters, where they have been previously stationed according to the regulations made by the captain. He orders and exhorts them every where to perform their duty;

and acquaints the captain at all other times of the misbehaviour of any person in the ship, and of whatever else concerns the service or discipline.

The youngest lieutenant in the ship, who is also styled *lieutenant at arms*, besides his common duty, is particularly ordered, by his instructions, to train the seamen to the use of small arms, and frequently to exercise and discipline them therein. Accordingly his office, in time of battle, is chiefly to direct and attend them; and at all other times to have a due regard to the preservation of the small arms, that they be not lost or embezzled, and that they are kept clean and in good condition for service.

LIEUTENANT-Reformed, he whose company or troop is broke or disbanded, but continued in whole or half-pay, and still preserves his right of seniority and rank in the army.

LIFE, is peculiarly used to denote the animated state of living creatures, or the time that the union of their soul and body lasts.

The *Prolongation of Life* is made by Lord Bacon one of the three branches of medicine; the other two relating to the preservation of health, and the cure of diseases. See **MEDICINE**.

The theory of prolonging life he numbers among the desiderata. Some means or indications that seem to lead to it, he lays down as follow.

Things are preserved in two manners; either in their *identity*, or by *reparation*. In their *identity*, as a fly or ant in amber; a flower, or fruit, or wood, in a conservatory of snow; a dead carcase in balsams. By *reparation*; as a flame, or a mechanical engine, &c. To attain to the prolongation of life, both these methods must be used. And hence, according to him, arise three intentions for the prolongation of life: *Retardation* of consumption, proper *reparation*, and *renovation* of what begins to grow old.

Consumption is occasioned by two kinds of depredation; a depredation of the innate spirit, and a depredation of the ambient air. These may be each prevented two ways; either by rendering those agents less predatory, or by rendering the passive parts (*viz.* the juices of the body) less liable to be preyed on. The spirit will be rendered less predatory, if either its substance be condensed, as by the use of opiates, grief, &c.; or its quantity diminished, as in spare and molar diets; or its motion calmed, as in idleness and tranquillity. The ambient air becomes less predatory, if it be either less heated by the rays of the sun, as in cold climates, in caves, mountains, and anchorets cells; or be kept off from the body, as by a dense skin, the feathers of birds, and the use of oils and unguents without aromatics. The juices of the body are rendered less liable to be preyed on, either by making them harder or more moist and oily; harder, as by a coarse sharp diet, living in the cold, robust exercises, and some mineral baths; softer, as by the use of sweet foods, &c. abstaining from salts and acids; and especially by such a mixture of drink as consists wholly of fine subtile particles, without any acrimony or acidity.

Reparation is performed by means of aliment; and alimentation is promoted four ways: By the concoction of the viscera, so as to extrude the aliment; By exciting the exterior parts to the attraction of the aliment; as in proper exercises and frictions, and some unctions and

Life,
Ligature.Ligature,
Light.

and baths : By the preparation of the food itself, so as it may more easily insinuate itself, and in some measure anticipate the digestion ; as in various ways of dressing meats, mixing drinks, fermenting breads, and reducing the virtues of these three into one : By promoting the act of assimilation itself, as in seasonable sleep, some external application, &c.

The *renovation* of what begins to grow old, is performed two ways : By the inteneration of the habit of the body ; as in the use of emollients, emplaisters, unguents, &c. of such a nature, as do not extract but impress : Or by purging off the old juices, and substituting fresh ones ; as in seasonable evacuations, attenuating diets, &c.

The same author adds these three axioms : That the prolongation of life is to be expected, rather from some stated diets, than either from any ordinary regimen or any extraordinary medicines ; more from operating on the spirits, and mollifying the parts, than from the manner of feeding ; and this mollifying of the parts without is to be performed by substantials, imprints, and occultants. See *LONGEVITY*.

Vegetable LIFE. See *PLANTS*.

LIFE-RENT, in Scots law. When the use and enjoyment of a subject is given to a person during his life, it is said to belong to him in life-rent.

LIGAMENT, in its general sense, denotes any thing that ties or binds one part to another.

LIGAMENT, in anatomy, a strong compact substance, serving to join two bones together. See *ANATOMY*, n^o 7.

LIGARIUS (Quintus), a Roman consul in Africa, 49 B. C. Taking part with Pompey, he was forced by Julius Cæsar to return to Rome : to obtain his pardon, Cicero made that admired oration in his defence which has immortalized the memory of the client with that of his celebrated advocate.

LIGATURE, in surgery, is a cord, band, or string ; or the binding any part of the body with a cord, band, fillet, &c. whether of leather, linen, or any other matter.

Ligatures are used to extend or replace bones that are broken or dislocated ; to tie the patients down in lithotomy and amputations ; to tie upon the veins in phlebotomy, on the arteries in amputations, or in large wounds ; to secure the splints that are applied to fractures ; to tie up the processes of the peritoneum with the spermatic vessels in castration ; and, lastly, in taking off warts or other excrescences by ligature.

LIGATURE, is also used to signify a kind of bandage or fillet, tied round the neck, arm, leg, or other part of the bodies of men or beasts, to divert or drive off some disease, accident, &c.

LIGATURE is also used for a state of impotency, in respect to venery, pretended to be caused by some charm or witchcraft.

Kæmpfer tells of an uncommon kind of ligature or knotting, in use among the people of Massacar, Java, Malaja, Siam, &c. By this charm or spell, a man binds up a woman, and a woman a man, so as to put it out of their power to have to do with any other person ; the man being thereby rendered impotent to any other woman, and all other men impotent with respect to the woman.

Some of their philosophers pretend, that this ligature may be effected by the shutting of a lock, the drawing of a knot, or the sticking of a knife in the wall, at the point of time wherein the priest is joining a couple together ; and that a ligature, thus effected, may be dissolved, by the spouse's unringing through a ring. This piece of superstition is said to obtain also among the Christians of the East.

The same author tells us, that during the ceremony of marriage in Russia, he observed an old fellow lurking behind the church-door, and mumbling over a string of words ; and, at the same time, cutting a long rod, which he held under his arm, into pieces ; which, it seems, is a common practice at the marriages of great persons, and done with design to elude and counterwork any other person that might possibly be inducing the ligature.

The secret of inducing a ligature is delivered by the same author, as he was taught it on the spot by one of their adepts : but it is too absurd and obscene to deserve being transcribed here.

M. Marshal mentions a ridiculous form of ligature, which he received from a bramin at Indostan : " If (says he) the little worm in the wood *lucurara kara* be cut into two, and the one part flirs and the other not, if the stirring part be bruised, and given with half a beetle to a man, and the other half to a woman, the charm will keep each from ever having to do with any other person." Phil. Trans. N^o 268.

LIGATURE, in the Italian music, signifies a tying or binding together of notes. Hence syncope are often called *ligatures*, because they are made by the ligature of many notes. There is another sort of ligatures for breves, when there are many of these on different lines, or on different spaces, to be sung to one syllable.

LIGATURES, among printers, are types consisting of two letters or characters joined together ; as *æ*, *ß*, *ff*, *ß*, *fi*. The old editions of Greek authors are extremely full of ligatures ; the ligatures of Stephens are by much the most beautiful.—Some editions have been lately printed without any ligatures at all ; and there was a design to explode them quite out of printing. Had this succeeded, the finest ancient editions would in time have grown useless ; and the reading of old manuscripts would have been rendered almost impracticable to the learned themselves.

LIGHT, in the most common acceptation of the word, signifies that invisible ethereal matter which makes objects perceptible to our sense of seeing. Figuratively, it is also used for whatever conveys instruction to our minds, and likewise for that instruction itself.

The nature of light hath been a subject of speculation from the earliest ages of philosophy. Some of the first those first distinguished by the appellation of philosophers even doubted whether objects became visible by means of any thing proceeding from them, or from the eye of the spectator. The fallacy of this notion must very soon have been apparent, because, in that case, we ought to have seen as well in the night as in the day. The opinion was therefore qualified by Empedocles and Plato ; who maintained, that vision was occasioned by particles continually flying off from the surfaces of bodies, which met with others proceeding from.

Light.

from the eye; but Pythagoras ascribed it solely to the particles proceeding from the external objects and entering the pupil of the eye.

2
Of Des
Cartes.

Among the modern philosophers there have been two celebrated opinions, *viz.* the Cartesian and Newtonian. According to the former, light is an invisible fluid present at all times and in all places, but which requires to be set in motion by an ignited or otherwise properly qualified body in order to make objects visible to us.—The Newtonians maintain, that light is not a fluid *per se*, but consists of a vast number of exceedingly small particles shaken off in all directions from the luminous body with inconceivable velocity by a repulsive power; and which most probably never return again to the body from which they were emitted. These particles are also said to be emitted in right lines by the body from whence they proceed: and this rectilinear direction they preserve until they are turned out of their original path by the attraction of some other body near which they pass, and which is called *inflection*; by passing through a medium of different density, which is called *refraction*, or by being thrown obliquely or directly forward by some body which opposes their passage, and which is called *reflection*; or, lastly, till they are totally stopped by the substance of any body into which they penetrate, and which is called their *extinction*. A succession of these particles following one another in an exactly straight line is called a *ray of light*; and this ray, in whatever manner it hath its direction changed, whether by refraction, reflection, or inflection, always preserves its rectilinear course; neither is it possible by any art whatever to make it pass on in the segment of a circle, ellipsis, or other curve.—From some observations on the eclipses of Jupiter's satellites, and also on the aberration of the fixed stars, it appears that the particles of light move at the rate of little less than 200,000 miles in a second of time. See *ASTRONOMY-Index*.

4
Objections
to the New-
tonian doc-
trine.

To this doctrine concerning the nature of light several objections have been made; the most considerable of which is, That in this case, as rays of light are continually passing in different directions from every visible point, they must necessarily interfere with and destroy each other in such a manner as entirely to confound all distinct perception of objects, if not to destroy the sense of seeing altogether; not to mention the continual waste of substance which a constant emission of particles must occasion in the luminous body, and which since the creation ought to have greatly diminished the sun and stars, as well as increased the bulk of the earth and planets by the vast quantity of particles of light absorbed by them in such a long period of time.

5
Answer by
Mr Mel-
ville.

In answer to this objection, Mr Melville gives some ingenious illustrations concerning the extreme subtilty of light, or the smallness of the particles of which it consists, and of which few persons, even of those who admit the hypothesis, have any idea. He observes, that there is probably no physical point in the visible horizon that does not send rays to every other point, unless where opaque bodies interpose. Light, in its passage from one system to another, often passes thro' torrents of light issuing from other suns and systems, without ever interfering or being diverted in its course, either by it, or by the particles of that elastic medium

which some phenomena give us reason to suppose are diffused through all the mundane space. To conclude, that the particles of which light consists must be incomparably rare, even when they are the most dense; that is, that the semidiameters of the two nearest particles, in the same or in different beams, soon after their emission, are incomparably less than their distance from one another. This difficulty concerning the non-interference of the particles of light is not solved, as he observes, by supposing with Mr Boscovich and others, that each particle is endued with an insuperable impulsive force; because, in that case, their spheres of impulsion would even be more liable to interfere, and they would on that account be more likely to disturb one another.

The difficulty, according to Mr Canton, will nearly vanish, if a very small portion of time be allowed between the emission of every particle and the next that follows in the same direction. Suppose, for instance, that one lucid point of the sun's surface emits 150 particles in a second, which are more than sufficient to give continual light to the eye without the least appearance of intermission; yet still the particles of which it consists, will on account of their great velocity be more than 1000 miles behind each other, and thereby leave room enough for others to pass in all directions.

In order to determine whether light really consists of particles emitted from the luminous body, or only in the vibrations of a subtle fluid, it has been attempted to find out its momentum, or the force with which it moves. The first who set about this matter with any tolerable pretensions to accuracy was M. Mairan. Others indeed, particularly Hartsoeker and Homburg, had pretended, that in certain cases this momentum was very perceptible; but M. Mairan proved, that the effects mentioned by them were owing to currents of heated air produced by the burning-glasses used in their experiments, or to some other causes overlooked by these philosophers. To decide the matter therefore, if possible, he began with trying the effects of rays collected by lenses of four and six inches diameter, and thrown upon the needle of a compass; but the result was nothing more than some tremulous motion from whence he could draw no conclusion. After this, he and Mr du Fay constructed a kind of mill of copper, which moved with an exceeding slight impulse; but though they threw upon it the focus of a lens of seven or eight inches diameter, they were still unable to draw any conclusions from the result.

M. Mairan afterwards procured a horizontal wheel of iron three inches in diameter, having fix radii, at the extremity of each of which was a small wing fixed obliquely. The axis of the wheel, which was also of iron, was suspended by a magnet. The wheel and the axis together did not weigh more than 30 grains; but though a motion was given to this wheel when the focus of the burning glass was thrown upon the extremities of the radii, yet it was so irregular, that he could not but conclude that it was occasioned by the motion of the heated air. He then intended to have made his experiment *in vacuo*, but he concluded that it was unnecessary. For, besides the difficulty of making a vacuum, he was persuaded that there was in our atmo-

Michell.

sphere a thinner medium which freely penetrates even glass itself, the existence of which he imagined that he had sufficiently proved in his treatise on the aurora borealis. See *AURORA BOREALIS*, n. 5.

Mr Michell some years ago endeavoured to ascertain the momentum of light in a manner still more accurate. The instrument he made use of for this purpose consisted of a very thin plate of copper, a little more than an inch square, which was fastened to one end of a slender harpichord-wire about ten inches long. To the middle of this was fixed an agate cap, such as is commonly used for small mariner's compasses, after the manner of which it was intended to turn; and at the other end of the wire was a middling sized shot-corn, as a counterpoise to the copperplate. The instrument had also fixed to it in the middle, at right angles to the length of the wire, and in an horizontal direction, a small bit of a very slender sewing-needle, about one-third or perhaps half an inch long, which was made magnetical. In this state the whole instrument might weigh about 10 grains. It was placed on a very sharp-pointed needle, on which the agate cap turned extremely freely; and to prevent its being disturbed by any motion of the air, it was included in a box, the lid and front of which were of glass. This box was about 12 inches long, six or seven inches deep, and about as much in width; the needle standing upright in the middle. At the time of making the experiment, the box was placed in such a manner that a line drawn from the sun passed at right angles to the length of it; and the instrument was brought to range in the same direction with the box, by means of the magnetical bit of needle above mentioned, and a magnet properly placed on the outside, which would retain it, though with extremely little force, in any situation. The rays of the sun were now thrown upon the copperplate above mentioned from a concave mirror of about two feet diameter, which, passing through the front-glass of the box, were collected into the focus of the mirror upon the copperplate. In consequence of this the plate began to move, with a slow motion of about an inch in a second of time, till it had moved through a space of about two inches and a half, when it struck against the back of the box. The mirror being removed, the instrument returned to its former situation by means of the little needle and magnet; and the rays of the sun being then again thrown upon it, it again began to move, and struck against the back of the box as before; and this was repeated three or four times with the same success.—The instrument was then placed the contrary way in the box to that in which it had been placed before, so that the end to which the copperplate was affixed, and which had lain, in the former experiment, towards the right hand, now lay towards the left; and the rays of the sun being again thrown upon it, it began to move with a slow motion, and struck against the back of the box as before; and this was repeated once or twice with the same success. But by this time the copperplate began to be so much altered in its form, by the extreme heat which it underwent in each experiment, and which brought it nearly into a state of fusion, that it became very much bent, and the more so as it had been unwarily supported by the middle, half of it lying above and half below the wire to which it was fastened. By this means it now varied

so much from the vertical position, that it began to act in the same manner as the sail of a windmill, being impelled by the stream of heated air which moved upwards, with a force sufficient to drive it in opposition to the impulse of the rays of light.

“If we impute (says Dr Priestley) the motion produced in the above experiment to the impulse of the rays of light, and suppose that the instrument weighed ten grains, and acquired a velocity of one inch in a second, we shall find that the quantity of matter contained in the rays falling upon the instrument in that time amounted to no more than one twelve-hundredth-millionth part of a grain, the velocity of light exceeding the velocity of one inch in a second in the proportion of about 12,000,000,000 to 1. Now the light in the above experiment was collected from a surface of about three square feet, which reflecting only about half what falls upon it, the quantity of matter contained in the rays of the sun incident upon a square foot and an half of surface in one second of time, ought to be no more than the twelve-hundred-millionth part of a grain, or, upon one square foot only, the eighteen-hundred-millionth part of a grain. But the density of the rays of light at the surface of the sun is greater than at the earth in the proportion of 45,000 to 1: there ought, therefore, to issue from one square foot of the sun's surface in one second of time, in order to supply the waste by light, one forty-thousandth part of a grain of matter; that is, a little more than two grains in a day, or about 4,752,000 grains, or 670 pounds avoirdupois nearly, in 6000 years; a quantity which would have shortened the sun's semidiameter no more than about ten feet, if it was formed of the density of water only.”

The Newtonians, besides the answer just now given to the most formidable objections of their opponents, have endeavoured to prove the impossibility of light being a vibration in any fluid. Sir Isaac, in his *Principia*, demonstrates, that no rectilinear motion can be propagated among the particles of any fluid unless these particles lie in right lines; and he hath also shown, that all motion propagated through a fluid diverges from a rectilinear progress into the unmoved spaces. Hence he concludes, “a pressure on a fluid medium (i. e. a motion propagated by such a medium beyond any obstacle, which impedes any part of its motion), cannot be propagated in right lines, but will be always infecting and diffusing itself every way, to the quiescent medium beyond that obstacle. The power of gravity tends downwards; but the pressure of water rising from it tends every way with an equable force, and is propagated with equal ease, and equal strength, in curves, as in straight lines. Waves, on the surface of the water, gliding by the extremes of any very large obstacle, infect and dilate themselves, still diffusing gradually, into the quiescent water beyond that obstacle. The waves, pulses, or vibrations of the air, wherein sound consists, are manifestly infected, though not so considerably as the waves of water; and sounds are propagated with equal ease, through crooked tubes and through straight lines; but light was never known to move in any curve, nor to infect itself *ad umbram*.”

To this Mr Rowning adds another proof. “The Cartesian notion of light (says he), was not that it is propagated from luminous bodies by the emission of small

By Mr
Rowning.

small

Light.

small particles, but that it was communicated to the organ of sight by their pressure upon the *materia subtilis*, with which they supposed the universe to be full. But, according to this hypothesis, it could never be dark; because, when a fluid sustains any pressure, if that fluid fills all the space it takes up, absolutely, without leaving any pores, which is the case of the supposed *materia subtilis*, then that pressure must necessarily be communicated *equally and instantaneously* to every part. And therefore, whether the sun were above or below the horizon, the pressure communicated, and consequently the light, would be the same. And farther, as the pressure would be instantaneous, so would the light, which is contrary to what is collected from the eclipses of Jupiter's satellites."

It is obvious, however, that whatever side we take concerning the nature of light, many, indeed almost all the circumstances concerning it, are incomprehensible, and beyond the reach of human understanding.

Most of the discous flowers, by some power unknown to us, follow the sun in his course. They attend him to his evening retreat, and meet his rising lustre in the morning with the same unerring law. If a plant also is shut up in a dark room, and a small hole is afterwards opened by which the light of the sun may enter, the plant will turn towards that hole, and even alter its own shape in order to get near it; so that though it was straight before, it will in time become crooked, that it may get near the light. It is not the *heat*, but the *light* of the sun, which it thus covets; for, though a fire be kept in the room, capable of giving a much stronger heat than the sun, the plant will turn away from the fire in order to enjoy the sun's light.—The green colour of plants also depends on the sun's light being allowed to shine upon them; for without this they are always white.—From this last circumstance, and likewise the property which the solar light has of blackening precipitates of silver from the nitrous acid*, it has been thought that light either contains the *phlogiston* in very considerable quantity, or is itself a modification of that unknown substance. But that this cannot be the case, we have now a proof little short of demonstration, from the last experiments of Dr Priestley concerning the production of pure dephlogisticated air from pump-water, by means of the solar light †. If light either were the *phlogiston* itself, or contained it in very considerable quantity, it is impossible the air produced by its means could be pure and dephlogisticated.—For the properties of light acting as the medium of our perceptions by the sense of sight, see the article *OPTICS*.

In the Philosophical Transactions for 1776, Dr Fordyce gives an account of some experiments upon the light produced by Inflammation. They were made to determine, whether there was any light produced by the inflammation itself, independent of ignition. Substances, he observes, begin to be luminous in the dark when heated to between 6 and 700 degrees of Fahrenheit's thermometer. If the substances be colourless, they first emit a red light; then a red mixed with yellow; and lastly, with a great degree of heat, a pure white. This whiteness, however, seems to depend greatly upon the density of the body; for the vapour at the end of the flame urged by a blow-pipe is not visibly luminous, though its heat be sufficiently great to

give a white heat to glass. The colour of the ignited matter, according to our author, has an effect upon the colour of the light emitted. Thus, during the calcination of zinc, the calx of which is white, a light is produced farce inferior in beauty to that of the sun himself. A beautiful green is communicated by its green calx of copper to the flame of a fire into which it is thrown; and the yellow empyreumatic oil into which tallow or any common oil is converted in burning, communicates a part of its own colour to the flame, which very much alters the appearance of bodies seen by candle-light from what it is by day-light. It does not, however, appear that this always holds good; for the flame of burning iron is intensely white; and yet neither the metal itself nor any of its calces are of that colour.

Light produced by the decomposition of bodies by inflammation without ignition is always blue, and produces very little heat. Thus phosphorus of urine is decomposed by mere exposure to the air, and gives but very little heat, though a considerable light is emitted. The following proof is adduced by our author that this emission of light is a true inflammation. "Take a receiver of white glass, capable of holding six or eight gallons; put into it a drachm of phosphorus finely powdered, and half an ounce of water; cork the mouth of the receiver, and tie it over with a bladder, so as to exclude the external air: incline the receiver to all sides gently, and afterwards set it to rest; the powder will adhere to the sides, and the water will drain from it. As soon as the water is sufficiently drained off, the particles of the phosphorus will become luminous, and emit a thick smoke: this will continue for some days; but at last no more light or vapour will appear. Open the receiver, and you will find that the air will have contracted, as it does from the inflammation of a candle in Van Helmont's experiment; that is, about a twentieth part. It is become unfit for inflammation; for if a lighted candle be immersed in it, it will be extinguished as well as the phosphorus, and an animal will be suffocated by it. The air then has suffered the same change as that which has served for the inflammation of other bodies; and the phosphorus is partly decomposed, the water in the receiver being impregnated with its acid, and the air saturated with its *phlogiston*. Blow fresh air into the receiver, and the light and smoke will immediately re-appear. In like manner it is known that sulphur will burn and give light without heat sufficient for ignition. Take a piece of iron heated nearly red hot, and throw a little gun-powder upon it. If the heat be of a proper degree, the sulphur will burn off with a blue flame, without heat sufficient for ignition; for if such heat had been produced, the gun-powder would certainly have taken fire. It is the inflammation and decomposition of the sulphur, and not its evaporation, which produces the light; for if we sublime sulphur in vessels of the most transparent glass, no light will be visible except at the very beginning, when a small portion of it burns till the air in the vessel be saturated, and rendered unfit for inflammation."

Our author is of opinion, that the light produced by inflammation is of a blue colour, from whatever body it is derived. This he endeavours to prove from an observation on the flame of a candle, the lower part of which, where the inflammation is, always appears of a blue

Light.

18

Light from inflammation is of a blue colour, from whatever body it is derived. This he endeavours to prove from an observation on the flame of a candle, the lower part of which, where the inflammation is, always appears of a blue

Light. a blue colour. "Or (says he) take a candle which has been burned for some time; extinguish it by applying tallow to the wick, and let it stand to cool; afterwards set it on fire by the flame of another candle; at first no more vapour will arise than can be acted upon by the air at once; inflammation, therefore, will go on in the whole small flame, and it will be blue. When a candle burns, the following process takes place. The tallow boils in the wick; and is converted into empyreumatic oil, rising from it in the form of vapour. As it rises from every part of the wick, the volume is increased till it comes to the top, and gives to the lower part of the flame the form of the frustum of an inverted cone. The air is applied to the outer surface of the column of vapour; and there decomposing the empyreumatic oil, produces heat and blue light: the stratum of vapour, within the outer burning surface, is heated white-hot; the heat diminishes towards the centre, which, if the flame be large, is scarcely red-hot; as the column rises, decomposition taking place constantly on its surface, it necessarily diminishes, and the upper part of the flame is conical. That the tallow boils in the wick, can be seen: that it is converted into empyreumatic oil, is proved by drawing the vapour, rising in the middle of the flame, where it does not burn, into a glass-tube: the empyreumatic oil condenses; this also shows that the flame does not burn in the middle. That the heat is produced on the outer surface, appears, if we take a small rod of glass, and put the end of it in the blue flame on the surface; it will be heated white-hot, and melt. Immerse the rod into the flame, so that the point shall be in the centre: it will melt and bend where it is in the blue flame on the surface; whereas, if the flame be large, the point which is in the centre will hardly be heated red-hot. That the empyreumatic oil is decomposed, is proved by burning a candle with a very small wick in distilling vessels; no condensation of empyreumatic oil takes place."

20 Mr Morgan's observations upon light.

In the 75th volume of the Transactions, Mr Morgan treats the subject of light at some length. As a foundation for his reasoning he assumes the following data. 1. That light is a body, and, like all others, subject to the laws of attraction. 2. That light is a heterogeneous body; and that the same attractive power operates with different degrees of force on its different parts. 3. That the light which escapes from combustible when decomposed by heat, or by any other means, was, previous to its escape, a component part of these substances. Hence he concludes, that when the attractive force by which the several rays of light are attached to a body is weakened, some of those rays will escape sooner than others; it being evident that those which are detained by the smallest power will soonest go off when the general attractive force is weakened. This he illustrates by the example of a mixture of spirit of wine, water, and other more fixed substances. The application of a gentle heat will carry off the spirit of wine only; a heat not much greater will evaporate the spirits and water mixed together; and a still greater degree will carry off a mixture of all the particles together. "In like manner (says he), when the surface of a combustible is in a state of decomposition, those parts of it which are the least fixed, or which are united with the least force, will be separated first. Amongst these the indigo rays of light will make the earliest appearance."

Vol. X. Part I.

By increasing the heat, we shall mix the violet with the indigo: by increasing it still more, we shall add the blue and the green to the mixture, till at length we reach that intensity of heat which will cause all the rays to escape at the same instant, and make the flame of a combustible perfectly white. By examining the flame of a common candle, we may observe, that its lowest extremities, or the part in which the black colour of the wick terminates, discharges the least heat; and that, as the vertex of the flame is approached, a successive order of parts is passed through, in which the lowest is continually adding to the heat of that which is just above it, till we come to the top of the flame, near which all the heat is collected into a focus. At the lowest extremity, however, where the heat is inconceivable, a blue colour may always be observed; and from this appearance, amongst others, I think it may be concluded, that the blue rays are some of those which escape from combustibles in an early period of their decomposition; and that if the decomposition could be examined in a period still more early, the colour of the flame would be violet. By an *à priori* deduction of this kind, I was led to observe, that to the external boundary of the flame of a common candle is annexed a filament of light; which if proper care be taken to prevent the escape of too much smoke, will appear most beautifully coloured with the violet and indigo rays. If sulphur or ether be burned, or any other combustible whose vapour is kindled in a small degree of heat, a blue flame will appear; which, if examined by the prism, will be found to consist of the violet, the indigo, the blue, and sometimes a small quantity of the green rays. The best mode, however, of showing the escape of some rays by that degree of heat which will not separate others till increased, is the following. Give a piece of brown paper a spherical form, by pressing it upon any hard globular substance. Gradually bring the paper thus formed to that distance from the candle at which it will begin to take fire. In this case a beautiful blue flame may be seen hanging, as it were, by the paper till a hole is made in it; when the flame, owing to the increased action of the air upon all parts of it, becomes white, though the edges still continue of a blue or violet colour. As a confirmation of this, it may be observed, that the very flame, which when exposed to a certain degree of heat emits only the most refrangible rays, will, if exposed to one considerably greater, emit also those which are less so. The flames of sulphur and spirit of wine, if suddenly exposed to the heat of a reverberatory, will change their blue colour for one that is perfectly white."

To obtain a more perfect knowledge of this matter, our author examined the light proceeding from combustible bodies by Mr Melville's method. Having darkened the room, he interposed betwixt the eye and combustible a sheet of pasteboard, in which was a very small hole for transmitting the light. Viewing the light which passed through this hole with a prism, he observed, that the blue and violet rays were in greater abundance than any of the rest, though all the different kinds passed through it when spirit of wine only was made use of. When the combustion of the spirit of wine was checked by throwing in sal ammoniac, the red rays disappeared, but made their appearance again as soon as the salt became heated to such a degree as to

Light. **27** Remarks on the flame of a candle.

23 Experiments on light by Mr Melville's method.

F increase

Light.

increase rather than diminish the combustion of the spirits. On examining the different parts of the flame separately, it was always found that the colours varied according to the degree of heat. At the base of the flame, or where the heat was least, the indigo, violet, and blue always appeared in greatest quantity; but as the vertex was approached, the other rays appeared, and at the very top they were all visible through a prism.

24
Conclusions
from these
experi-
ments.

From these facts Mr Morgan concludes, 1. That light, as an heterogeneous body, is gradually decomposed during combustion; that the indigo rays escape with the least heat, and the red with the greatest; and from this again he explains the reason why flames assume different colours. "If a piece of paper (says he), impregnated with a solution of copper in nitrous acid, be set on fire, the bottom and sides of the flame are always tinged green. Now this flame is evidently in that weak state of decomposition in which the most refrangible rays escape in the greatest abundance; but of these the green rays escape most plentifully through the unignited vapour and that portion of the atmosphere which is interposed betwixt the eye and the flame. This peculiarity may be observed in greatest perfection in brass foundries. Here the heat, though very strong, is scarcely sufficient to decompose the metallic vapour which escapes from the melted brass; whence the flame has a very singular appearance, the edges being green, and the body of such an appearance, as to give substances viewed by it a pallid and ghastly appearance, owing to the want of a sufficient quantity of red rays to make a perfect white."

25
Red ap-
pearance of
bodies in
their last
state of ig-
nition ex-
plained.

2. Mr Morgan explains the red appearance of bodies in their last state of ignition, from the previous escape of the more refrangible rays, so that only the red ones remain. "Again, (says he), we may consider the external surface of the combustible body as annexed to an inner surface, which may be partly, but not so perfectly decomposed as itself: for the violence of the heat will be found to lessen in its effects the nearer it approaches to the centre of the substance which is exposed to it. Hence we are to consider the parts which are just covered by the external surface as having lost less of their component light than the external surface itself; or the former may retain the green rays when the latter has lost both indigo, violet, blue, and green.

3. "Those parts which are nearer the centre of the body than any of the preceding, must, as they are farther from the greatest violence of the heat, have lost proportionably fewer of their rays; or while the external parts may have lost all but the red, these may have lost only the indigo and violet.

4. "The most central parts may be unaffected by the heat; and whenever the fire does reach these parts, they will immediately discharge their indigo rays, and be decomposed in the gradual manner already mentioned. A piece of rotten wood, while burning, will exemplify and confirm the preceding illustration. When influenced by the external air only, if examined through a prism, no rays will be found to escape but the orange and the red. By blowing upon the burning wood with a pair of bellows, the combustion being increased, will affect those internal parts of the body which were not acted upon before. These parts therefore will begin to lose their light, and a prism will show the green, blue, violet, and indigo, all appearing in succession. Ap-

pearances similar to the preceding may be observed in a common kitchen fire. When it is faintest, its colour is most red, the other rays having been emitted, and the combustion at a stand; but by blowing upon it in this state, its brightness will be increased, and more and more of the rays which are yielded by the internal parts of the body will come to the eye, till at length, by continuing to blow, the combustion will be made so complete as to yield all the rays, or to make it appear perfectly white."

Our author concludes the subject with a criticism upon Sir Isaac Newton's definition of flame, viz. Newton's definition of flame is an instance of combustion whose colour will be determined by the degree of decomposition which takes place. When very imperfect, only the most refrangible rays will appear. If it be very perfect, all the rays will appear, and its flame will be brilliant in proportion. But there are flames which consist of burning particles, the rays of which have partly escaped before they ascended in form of vapour. "Such (says he) would be the flame of a red hot coal, if exposed to such a heat as would gradually convert it into vapour. When the fire is very low under the furnace of an iron foundry, at the upper orifice of the chimney a red flame of this kind may be seen, which is different from the flame that appears immediately after fresh coals have been thrown upon the fire; for in consequence of adding such a supply to the burning fuel, a vast column of smoke ascends, and forms a medium so thick as to absorb most of the rays excepting the red."

Thus we have a most elaborate theory for the solving of phenomena which seem not easily to admit of any solution. It is obvious, however, that the theory upon which he builds his system are altogether unfounded and hypothetical. That light is subject to the laws of attraction, cannot be proved unless we could examine it independent of any other substance whatever; that is to say, in a perfect vacuum; and even in the most perfect vacuum that can be formed, we are far from being certain that no other matter is present. Light is inflected and turned out of its course in many different ways when acting in the common atmosphere, but we have no reason to suppose that it would be the same in a perfect vacuum; at least we have not a right to lay it down as a principle to argue from, unless it were verified by experience. Even the heterogeneous nature of light seems far from being absolutely established. The refraction into different colours by the prism seems insufficient to do so; for though, by a quick revolution of these colours when painted upon any substance, we may produce a kind of white colour, it is by no means perfect, but looks as if some black had got amongst it. The opinion of those who maintain that the prismatic colours are no other than different mixtures of light and shade, seems therefore equally probable with the other. His third position, that the light emitted by combustible bodies formed part of their substance before combustion, seems still worse founded; for instead of being fixed in solid substances, all the light and heat proceeding from combustion seem entirely to come from the air. By means of heat originally applied, the substance, or part of it, is raised into vapour; and this vapour, we have every reason to suppose, consists of elementary fire united with the solid substance. It is this fire, heat, or light, which

ed.

^{Light} is afterwards thrown out from the vapour in combustion; and new supplies of it perpetually come from the atmosphere, as is abundantly shown under the articles COMBUSTION, FIRE, FLAME, and many others throughout this work. We cannot therefore think it either inconsistent, or very improbable, that in the beginning of combustion, when the *subtile* light is clouded with a great quantity of vapour, it should appear of a blue or violet colour; and that in proportion as this vapour is dissipated, it should appear green, yellow, red, or perfectly white: for it is observable, that in dephlogisticated air, even those flames which in the common atmosphere always appear blue, such as sulphur and spirit of wine, are then changed to a dazzling white. The pure light of the sun also seen through smoke, or even through a great quantity of aqueous vapour, appears red; and there is not the least doubt, that if we were to view the sun while he thus appears red through any blue medium, he would appear purple; and in like manner, were we to view a blue flame through a yellow medium, it would appear of a green colour.

²⁸
His observations on electric light.

In the fame paper Mr Morgan has some curious observations upon the electric light. There is neither fluid nor solid, he says, through which the electric fluid in its passage will not appear luminous, if we do not make the quantity, through which it has to pass, too great. In his experiments on fluids, he puts them into a tube about three quarters of an inch diameter and four inches long. The orifices are then stopped up with two corks, through which two pointed wires are thrust, so that the points may approach within one eighth part of an inch of each other; and in this case the electric matter which passes through the fluid is always luminous, provided a sufficient force be used. The experiment, however, is dangerous, unless great care be taken; and the tube, unless it be very strong, will be broken by a very slight discharge. With acids the experiment succeeds more difficultly; they must be put into capillary tubes, and the wires placed very near to each other. A strip of gold leaf one eighth of an inch diameter, and a yard long, becomes quite luminous by discharging a battery over it; and our author cannot ascertain the length to which it might be made luminous. The experiment will also succeed with Dutch metal or silver leaf. If the gold or silver leaf be put upon a glass, and that laid in water, the whole will appear most beautifully luminous on discharging a battery through it.

The better a conductor that any substance is, the greater is the difficulty of making the electric spark visible in it. Hence it requires a much greater power of electricity to make a spark visible in boiling than in cold water; the former being a much better conductor than the latter. In like manner, the mineral acids are much better conductors than common water; and, of consequence, the spark is made to appear in them with much more difficulty than in water. This appears from what has been already mentioned; and our author likewise observes, that if a few drops of acid be poured into the tube containing the water employed for this purpose, it will scarcely be possible to make the spark luminous in it by any force.

The rarity of any body greatly increases the ease with which the electric spark is made visible in it; as

^{Light} appears from discharging a vial through rarefied air, the vapour of ether, spirit of wine, or water.

In the prosecution of his experiments upon this subject, our author cemented a ball of iron into the orifice of a tube 48 inches long, and two thirds of an inch diameter, so that it could bear the weight of the quicksilver with which the tube was filled all to a small space at the open end, which contained a few drops of water. Having inverted the tube, and plunged the open end of it into a basin of mercury, that in the tube stood nearly half an inch lower than in a barometer with which it was compared at the same time, owing to the vapour which was formed by the water; but the spark passed as brilliant through the rarefied water as it does through rarefied air. If spirit of wine be employed instead of water in this experiment, the spark will not be so luminous. In the vapour of ether a great force is requisite to make the spark luminous, but good ether will press the mercury down as far as 16 or 17 inches. By rarefying the vapour, however, the spark will pass through it with more ease.

On examining the mineral acids *in vacuo*, Mr Morgan could not find that any vapour escaped from them. To give them the requisite degree of tenuity, therefore, he traced a line upon glass about an eighth part of an inch broad, with a camel's hair pencil dipped in the acids: the line extended sometimes to the length of 27 inches; in which case, the electric spark would pass over the whole with great brilliancy. If by widening the line, however, or putting on a drop of acid in any particular part, the quantity was increased, the spark never appeared in that part.

The brightness of the electric light is always in proportion to its condensation. Thus, if a spark taken from a powerful electrical machine divides itself into brushes, or throws out sparks from the sides, by which the light is diffused over a larger surface, it thus becomes less brilliant; and in all cases in which any diffusion of light, whether electric or not, takes place, the case will be the same.

In some cases, Mr Morgan is of opinion, that, even with the electric fluid, only the more refrangible rays of light make their escape. Thus, the electrical brush is always of a purplish or bluish colour; and if you convey a spark through a Torricellian vacuum not very perfectly made, it will be of an indigo colour. This, however, does not seem to arise from any other cause than the mere weakness of the light, which, in passing through the vapours of the atmosphere, or perhaps through the humours of the eye itself, affects our organs of sight in that manner.

Our author next proceeds to examine the influence of media upon electric light; which, he says, is similar media upon their influence upon solar light, and serves to explain several phenomena.

“Let a pointed wire (says he), having a metallic ball fixed to one of its extremities, be forced obliquely into a piece of wood, so as to make a small angle with its surface; and to make the point lie about one eighth of an inch below it. Let another pointed wire, which communicates with the ground, be forced in the same manner into the same wood, so that its point may in like manner be about one eighth of an inch below the surface, and about two inches distant from the point

32
Curious experiment of sending the electric spark thro' wood.

of the first wire. Let the wood be insulated, and a strong spark, which strikes on the metallic ball, will force its way through the interval of wood which lies between the points, and appear as red as blood. To prove that this appearance depends on the wood's absorption of all the rays but the red, I would observe, that the greater the depth of the points is below the surface, the less mixed are the rays. When they are deeper below the surface, only the red come to the eye through a prism; when raised a little nearer the surface, the red and orange appeared; when nearer still, the yellow; and so on, till, by making the spark pass through the wood very near its surface, all the rays were at length able to reach the eye. If the points be only one eighth of an inch below the surface of soft deal wood, the red, the orange, and the yellow rays will appear as the spark passes through it. But when the points are at an equal depth in a piece of harder wood, box for instance, the yellow, and perhaps the orange, will disappear. As a farther proof of this absorption of the rays, it may be observed, when the spark strikes very bright upon one side of the piece of deal, it will appear quite red on the other. In like manner, a red appearance may be given to a spark which strikes bright over the inside of a tube, merely by spreading some pitch very thinly over the outside of the same tube."

33
Different appearance of the electric spark at different distances.

Mr Morgan now proceeds to mention some experiments which seem to militate against the doctrine he has been endeavouring to establish, rather than to support it; viz. 1. If into a Torricellian vacuum of any length a few drops of ether are conveyed, and both ends of the vacuum stopped up with metallic conductors, so that a spark may pass through it, the spark in its passage will make the following appearances. When the eye is placed close to the tube, the spark will appear perfectly white; if the eye is removed to the distance of two yards, it will appear green; but at the distance of six or seven yards, it will appear reddish. "These changes evidently depend (says our author) on the quantity of medium through which the light passes; and the red light more particularly, which we see at the greatest distance from the tube, is accounted for on the same principle as the red light of the beclouded sun, or a lighted candle."

2. Dr Priestley long ago observed the red appearance of the electric spark, when passing through inflammable air. But this appearance is very much diversified according to the quantity of medium through which the spark is beheld. At a very considerable distance the red comes unmixed to the eye; but if the eye be placed close to the tube, the spark appears white and brilliant. By increasing, however, the quantity of fluid conveyed through any portion of inflammable air, or by condensing that air, the spark may be made perfectly white. It may further be observed, that all weak explosions and sparks, when viewed at a distance, make a reddish appearance. The reason of these appearances seems to be, that the weaker the spark or explosion is, the more it is disposed to assume a red colour when viewed at a distance. This seems to confirm what has already been mentioned as a probable hypothesis, that the different colours of light are entirely owing to the medium through which they are viewed.

Light.

33
Observations on phosphoric light.
* See Phosphorus.

On phosphoric light Mr Morgan makes some curious observations; but still argues on the same principles we have already mentioned. "Some shells (says he), prepared according to Mr Wilson's directions", after being exposed to the sun, or to the fash of a battery, emit a purple, others a green, and others a reddish light. If, with Mr Wilson, we suppose that these shells are in a state of slow combustion, may we not conclude that some are just beginning to burn, and therefore emitting the most refrangible rays; while others are in a more advanced state of combustion, and therefore emitting the least refrangible? If this conclusion be right, the shells which are emitting the purple or the green, must still retain the yellow, the orange, and the red, which will also make their appearance as soon as the combustion is sufficiently increased." In confirmation of this, Mr Morgan adduces the following experiment, viz. that if a shell, while emitting its green rays, be placed upon a warm shovel, the colour will soon be changed into a yellow mixed with red.—To the theory of slow combustion Mr Morgan makes the following objections.

1. If phosphoric shells owe their light to this cause, we must consider the word combustion, when applied to them, as implying all those circumstances which usually attend a body when on fire. On this supposition there ought to be an increase of the heat as well as of the decomposition of the combustible. But neither of these are found to take place in fact; for a phosphoric body never fails to lose its light entirely in a certain degree of heat, without losing the power of becoming phosphoric again when it has been sufficiently cooled. While very hot, the charge of the strongest battery conveyed over it has no effect.

2. When bodies are wasted by combustion, they can never be made to reassume the appearances which they previously displayed. "No power (says our author) can give to ashes the phenomena of a burning coal. But phosphoric bodies are very different in this respect; for a phosphoric shell may be made to lose all its light by exposure to heat, and again may be made as luminous as ever by exposure to the sun."

3. It is remarkable that some bodies which are most beautifully phosphoric, are at the same time the most obstinate in resisting fire. "Let us now see (says Mr Morgan) the consequence of admitting the common hypothesis, that the detention of those rays which fall upon phosphori is owing to some force which prevents their immediate reflection, but is not adequate to their entire absorption. This force, whatever it be, cannot well be supposed to operate with equal power on all these rays. If this be not the case, we cannot well avoid concluding, that phosphoric shells will assume different colours, owing to the earlier and later escape of the different rays of light. This conclusion is justified by an experiment already mentioned; viz. that when the force is such as to admit the escape of the purple, blue, and green, we have only to lessen that force, by warming the body, and the yellow, the orange, and red escape. Beccaria has proved, that there is scarcely any body which is not phosphoric, or may not become so by heat. But as the phosphoric force is most powerful when the purple rays only escape, so we are to conclude, that it is weakest when it is able to retain the red rays only. This is agreeable to several facts.

Light.

Chalk, oyster-shells, together with those phosphoric bodies whose goodness has been very much impaired by long keeping, when finely powdered, and placed within the circuit of an electrical battery, will exhibit, by their scattered particles, a shower of light; but these particles will appear reddish, or their phosphoric power will be sufficient only to detain the yellow, orange, and red rays. When spirit of wine is in a similar manner brought within the circuit of a battery, a similar effect may be discovered: its particles diverge in several directions, displaying a most beautiful golden appearance. The metallic calces are rendered phosphoric with the greatest difficulty; but even these may be scattered into a shower of red luminous particles by the electric stroke."

In a postscript to this paper, by Dr Price, it is observed, that by *phosphoric force*, Mr Morgan seems to mean, not the force with which a phosphoric body emits, but that with which it *absorbs and retains*, the light. This last force is proportioned to the degree of attraction between the phosphoric body and light; and therefore must, according to Mr Morgan's theory, be weakest when it so freely emits the light it has imbibed as not to retain those rays which adhere to it most strongly. According to Mr Morgan's theory, there are the rays which are the least refrangible. "It is, however (says Dr Price), an objection to it, that the less refrangibility of rays seems to imply a less force of attraction between them and the substances which refract them; but it should be considered, that, possibly, the force of cohesion, which unites the rays of light to bodies, may be a different power from that which refracts them."

Light independent of Heat. In general, a very considerable degree of heat is requisite to the emission of light from any body; but there are several exceptions to this, especially in light proceeding from putrescent substances and phosphorus, together with that of luminous animals, and other similar appearances. Light proceeding from putrescent animal and vegetable substances, as well as from glow-worms, is mentioned by Aristotle. Thomas Bartholin mentions four kinds of luminous insects, two with wings, and two without; but in hot climates travellers say they are found in much greater numbers, and of different species. Columna, an industrious naturalist, observes, that their light is not extinguished immediately upon the death of the animal.

The first distinct account that we meet with of light proceeding from putrescent animal-flesh is that which is given by Fabricius ab Aquapendente; who says, that when three Roman youths, residing at Padua, had bought a lamb, and had eaten part of it on Easter day 1592, several pieces of the remainder, which they kept till the day following, shone like so many candles when they were casually viewed in the dark. Part of this luminous flesh was immediately sent to Aquapendente, who was professor of anatomy in that city. He observed, that both the lean and the fat of this meat shone with a whitish kind of light; and also took notice, that some pieces of kid's flesh, which had happened to have lain in contact with it, was luminous, as well as the fingers and other parts of the bodies of those persons who touched it. Those parts, he observed, shone the most which were soft to the touch, and seemed to be transparent in candle light; but

where the flesh was thick and solid, or where a bone was near the outside, it did not shine.

After this appearance, we find no account of any other similar to it, before that which was observed by Bartholin, and of which he gives a very pompous description in his ingenious treatise already quoted. This happened at Montpelier in 1641, when a poor old woman had bought a piece of flesh in the market, intending to make use of it the day following. But happening not to be able to sleep well that night, and her bed and pantry being in the same room, she observed so much light come from the flesh, as to illuminate all the place where it hung. A part of this luminous flesh was carried as a curiosity to Henry Bourbon, duke of Condé, the governor of the place, who viewed it for several hours with the greatest astonishment.

This light was observed to be whitish; and not to cover the whole surface of the flesh, but certain parts only, as if gems of unequal splendor had been scattered over it. This flesh was kept till it began to putrify, when the light vanished; which, as some religious people fancied, it did in the form of a cross.

It is natural to expect, that the almost universal experimental philosopher Mr Boyle should try the effect of his air-pump upon these luminous substances. Accordingly we find that he did not fail to do it; when he presently found that the light of rotten wood was extinguished in *vacuo*, and revived again on the admission of the air, even after a long continuance in *vacuo*; but the extinguishing of this light was not so complete immediately upon exhausting the receiver, as some little time afterwards. He could not perceive, however, that the light of rotten wood was increased in condensed air; but this, he imagined, might arise from his not being able to judge very well of the degree of light, through so thick and cloudy a glass-vessel as he then made use of; but we find that the light of a shining fish, which was put into a condensing engine before the Royal Society, in 1668, was rendered more vivid by that means. The principal of Mr Boyle's experiments were made in October 1667.

This philosopher attended to a great variety of circumstances relating to this curious phenomenon. Among other things he observed, that change of air was not necessary to the maintenance of this light; for it continued a long time when a piece of the wood was put into a very small glass hermetically sealed, and it made no difference when this tube which contained the wood was put into an exhausted receiver. This he also observed with respect to a luminous fish, which he put into water, and placed in the same circumstances. He also found, that the light of shining fishes had other properties in common with that of shining wood; but the latter, he says, was presently quenched with water, spirit of wine, a great variety of saline mixtures, and other fluids. Water, however, did not quench all the light of some shining veal on which he tried it, though spirit of wine destroyed its virtue presently.

Mr Boyle's observation of light proceeding from flesh-meat was quite casual. On the 15th of February 1662, one of his servants was greatly alarmed with the shining of some veal, which had been kept a few days, but had no bad smell, and was in a state very proper for use. The servant immediately made his master acquainted with this extraordinary appearance

ance; and though he was then in bed, he ordered it to be immediately brought to him, and he examined it with the greatest attention. Suspecting that the state of the atmosphere had some share in the production of this phenomenon, he takes notice, after describing the appearance, that the wind was south-west and blustering, the air hot for the season, the moon was past its last quarter, and the mercury in the barometer was at $29\frac{1}{2}$ inches.

35
Light from
fishes.

Mr Boyle was often disappointed in his experiments on shining fishes; finding that they did not always shine in the very same circumstances, as far as he could judge, with others which had shined before. At one time that they failed to shine, according to his expectations, he observed that the weather was variable, and not without some days of frost and snow. In general he made use of whittings, finding them the fittest for his purpose. In a discourse, however, upon this subject at the Royal Society in 1681, it was asserted, that, of all fishy substances, the eggs of lobsters, after they had been boiled, shone the brightest. Olig. Jacobæus observes, that, upon opening a sea-polypus, it was so luminous, as to startle several persons who saw it; and he says, that the more putrid the fish was, the more luminous it grew. The nails also, and the fingers of the persons who touched it, became luminous; and the black liquor which issued from the animal, and which is its bile, shone also, but with a very faint light.

As. Hafs.
vol. v.
p. 282.

Mr Boyle draws a minute comparison between the light of burning coals and that of shining wood or fish, showing in what particulars they agree, and in what they differ. Among other things he observes, that extreme cold extinguishes the light of shining wood, as appeared when a piece of it was put into a glass tube, and held in a frigorific mixture. He also found that rotten wood did not waite itself by shining, and that the application of a thermometer to it did not discover the least degree of heat.

36
Of the pho-
las, a re-
markably
luminous
fish.

There is a remarkable shell-fish called PHOLAS, which forms for itself holes in various kinds of stone, &c. That this fish is luminous, was noticed by Pliny; who observes, that it shines in the mouth of the person who eats it, and, if it touch his hands or cloaths, makes them luminous. He also says that the light depends upon its moisture. The light of this fish has furnished matter for various observations and experiments to M. Reaumur, and the Bolognian academicians, especially Beccarius, who took so much pains with the subject of phosphoreal light.

M. Reaumur observes, that, whereas other fishes give light when they tend to putrefescence, this is more luminous in proportion to its being fresh; that when they are dried, their light will revive if they be moistened either with fresh or salt water, but that brandy immediately extinguishes it. He endeavoured to make this light permanent, but none of his schemes succeeded.

The attention of the Bolognian academicians was engaged to this subject by M. F. Marilius, in 1724, who brought a number of these fishes, and the stones in which they were inclosed, to Bologna, on purpose for their examination.

Com. Bonon.
vol. ii. 232.

Beccarius observed, that though this fish ceased to shine when it became putrid; yet that in its most putrid state, it would shine, and make the water in which

it was immersed luminous, when they were agitated. Galeatus and Montius found, that wine or vinegar extinguished this light: that in common oil it continued some days; but in rectified spirit of wine or urine, hardly a minute.

In order to observe in what manner this light was affected by different degrees of heat, they made use of a Reaumur's thermometer, and found that water rendered luminous by these fishes increased in light till the heat arrived to 45 degrees; but that it then became suddenly extinct, and could not be revived.

In the experiments of Beccarius, a solution of sea-salt increased the light of the luminous water, a solution of nitre did not increase it quite so much. Sal ammoniac diminished it a little, oil of tartar *per deliquium* nearly extinguished it, and the acids entirely. This water poured upon fresh calcined gypsum, rock crystal, cerus, or sugar, became more luminous. He also tried the effects of it when poured upon various other substances, but there was nothing very remarkable in them. Afterwards, using luminous milk, he found that oil of vitriol extinguished the light, but that oil of tartar increased it.

This gentleman had the curiosity to try how differently coloured substances were affected by this kind of light; and having, for this purpose, dipped several ribbons in it, the white came out the brightest, next to this was the yellow, and then the green; the other colours could hardly be perceived. It was not, however, any particular colour, but only light that was perceived in this case. He then dipped boards painted with the different colours, and also glass tubes, filled with substances of different colours, in water rendered luminous by the fishes. In both these cases the red was hardly visible, the yellow was the brightest, and the violet the dullest. But on the boards the blue was nearly equal to the yellow, and the green more languid; whereas in the glasses, the blue was inferior to the green.

Of all the liquors into which he put the pholades, milk was rendered the most luminous. A single pholas made seven ounces of milk so luminous, that the faces of persons might be distinguished by it, and it looked as if it was transparent.

Air appeared to be necessary to this light; for when Beccarius put the luminous milk into glass tubes, no agitation would make it shine, unless bubbles of air were mixed with it. Also Montius and Galeatus found, that, in an exhausted receiver, the pholas lost its light, but the water was sometimes made more luminous; which they ascribed to the rising of bubbles of air through it.

Beccarius, as well as Reaumur, had many schemes to render the light of these pholades permanent. For this purpose he kneaded the juice into a kind of paste, with flour, and found that it would give light when it was immersed in warm water; but it answered best to preserve the fish in honey. In any other method of preservation, the property of becoming luminous would not continue longer than six months, but in honey it had lasted above a year; and then it would, when plunged in warm water, give as much light as ever it had done.

Similar, in some respects, to those observations on the light of the pholas, was that which was observed

to proceed from wood which was moist, but not in a putrid state, which was very conspicuous in the dark.

That the sea is sometimes luminous, especially when it is put in motion by the dashing of oars or the beating of it against a ship, has been observed with admiration by a great number of persons. Mr Boyle, after reciting all the circumstances of this appearance, as far as he could collect them from the accounts of navigators; as its being extended as far as the eye could reach, and at other times being visible only when the water was dashed against some other body; that, in some seas, this phenomenon is accompanied by some particular winds, but not in others; and that sometimes one part of the sea will be luminous, when another part, not far from it, will not be so; concludes with saying, that he could not help suspecting that these odd phenomena, belonging to great masses of water, were in some measure owing to some cosinical law or cullom of the terrestrial globe, or at least of the planetary vortex.

Some curious observations on the shining of some fishes, and the pickle in which they were immerged, were made by Dr Beal, in May 1665; and had they been properly attended to and pursued, might have led to the discovery of the cause of this appearance. Having put some boiled mackerel into water, together with salt and sweet herbs; when the cook was, some time after, stirring it, in order to take out some of the fishes, he observed, that, at the first motion, the water was very luminous; and that the fish shining through the water added much to the light which the water yielded. The water was of itself thick and blackish, rather than of any other colour; and yet it shined on being stirred, and at the same time the fishes appeared more luminous than the water. Wherever the drops of this water, after it had been stirred, fell to the ground, they shined; and the children in the family diverted themselves with taking the drops, which were as broad as a penny, and running with them about the house. The cook observed, that, when she turned up that side of the fish that was lowest, no light came from it; and that, when the water had settled for some time, it did not shine at all. The day following, the water gave but little light, and only after a brisk agitation, though the fishes continued to shine as well from the inside as the outside, and especially about the throats, and such places as seemed to have been a little broken in the boiling.

When, in the light of the sun, he examined, with a microscope, a small piece of a fish which had shined very much the night before, he found nothing remarkable on its surface, except that he thought he perceived what he calls a *steam*, rather dark than luminous, arising like a very small dust from the fish, and here and there a very small and almost imperceptible spark. Of the sparkles he had no doubt; but he thought it possible that the steam might be a deception of the sight, or some dust in the air.

Finding the fish to be quite dry, he moistened it with his spittle; and then observed that it gave a little light, though but for a short time. The fish at that time was not fed, nor yet insipid to the best discerning palate. Two of the fishes he kept two or three days longer for farther trial: but, the weather being very hot, they became fetid; and, contrary to his ex-

pectations, there was no more light produced either by the agitation of the water or in the fish.

Father Bourzes, in his voyage to the Indies in 1704, took particular notice of the luminous appearance of the sea. The light was sometimes so great, that he could easily read the title of a book by it, though he was nine or ten feet from the surface of the water. Sometimes he could easily distinguish, in the wake of the ship, the particles that were luminous from those that were not; and they appeared not to be all of the same figure. Some of them were like points of light, and others such as stars appear to the naked eye. Some of them were like globes, of a line or two in diameter; and others as big as one's head. Sometimes they formed themselves into squares of three or four inches long, and one or two broad. Sometimes all these different figures were visible at the same time; and sometimes there were what he calls *vortices* of light, which as one particular time appeared and disappeared immediately like flashes of lightning.

Nor did only the wake of the ship produce this light, but fishes also, in swimming, left so luminous a track behind them, that both their size and species might be distinguished by it. When he took some of the water out of the sea, and stirred it ever so little with his hand, in the dark, he always saw in it an infinite number of bright particles; and he had the same appearance whenever he dipped a piece of linen in the sea, and wrung it in a dark place, even though it was half dry; and he observed, that when the sparkles fell upon any thing that was solid, it would continue shining for some hours together.

After mentioning several circumstances which did not contribute to this appearance, this Father observes, that it depends very much upon the *quality of the water*, and he was pretty sure that this light is the greatest, when the water is fattest, and fullest of foam. For in the main sea, he says, the water is not everywhere equally pure; and that sometimes, if linen be dipped in the sea, it is clammy when it is drawn up again; and he often observed, that when the wake of the ship was the brightest, the water was the most fat and glutinous, and that linen moistened with it produced a great deal of light, if it was stirred or moved briskly. Besides, in some parts of the sea, he saw a substance like saw-dust, sometimes red and sometimes yellow; and when he drew up the water in those places, it was always viscous and glutinous. The sailors told him, that it was the spawn of whales; that there are great quantities of it in the north; and that sometimes, in the night, they appeared all over of a bright light, without being put in motion by any vessel or fish passing by them.

As a confirmation of this conjecture, that the more glutinous the sea-water is, the more it is disposed to become luminous, he observes, that one day they took a fish which was called a *bonite*, the inside of the mouth of which was so luminous, that, without any other light, he could read the same characters which he had before read by the light in the wake of the ship; and the mouth of this fish was full of a viscous matter, which, when it was rubbed upon a piece of wood, made it immediately all over luminous; though, when the moisture was dried up, the light was extinguished.

The abbé Nollet was much struck with the lumi-

let's theory.

nousness of the sea when he was at Venice in 1749; and, after taking a great deal of pains to ascertain the circumstances of it, concluded that it was occasioned by a shining insect; and having examined the water very often, he at length did find a small insect, which he particularly describes, and to which he attributes the light. The same hypothesis had also occurred to M. Vianelli, professor of medicine in Chioggia near Venice; and both he and M. Grizzolini, a physician in Venice, have given drawings of the insects from which they imagined this light to proceed.

The abbé was the more confirmed in his hypothesis, by observing, some time after, the motion of some luminous particles in the sea. For, going into the water, and keeping his head just above the surface, he saw them dart from the bottom, which was covered with weeds, to the top, in a manner which he thought very much resembled the motions of insects; though, when he endeavoured to catch them, he only found some luminous spots upon his handkerchief, which were enlarged when he pressed them with his finger.

42
Observa-
tions of M.
le Roi.

M. le Roi, making a voyage on the Mediterranean, presently after the abbé Nollet made his observations at Venice, took notice, that in the day-time, the prow of the ship in motion threw up many small particles, which, falling upon the water, rolled upon the surface of the sea for a few seconds before they mixed with it; and in the night the same particles, as he concluded, had the appearance of fire. Taking a quantity of the water, the same small sparks appeared whenever it was agitated; but, as was observed with respect to Dr Beal's experiments, every successive agitation produced a less effect than the preceding, except after being suffered to rest a while; for then a fresh agitation would make it almost as luminous as the first. This water, he observed, would retain its property of shining by agitation a day or two; but it disappeared immediately on being set on the fire, though it was not made to boil.

Memoirs
Presentes,
vol. III. 144.

This gentleman, after giving much attention to this phenomenon, concludes, that it is not occasioned by any shining insects, as the abbé Nollet imagined; especially as, after carefully examining some of the luminous points, which he caught upon an handkerchief, he found them to be round like large pins heads, but with nothing of the appearance of any animal, though he viewed them with a microscope. He also found, that the mixture of a little spirit of wine with water just drawn from the sea, would give the appearance of a great number of little sparks, which would continue visible longer than those in the ocean. All the acids, and various other liquors, produced the same effect, though not quite so conspicuously; but no fresh agitation would make them luminous again. M. le Roi is far from asserting that there are no luminous insects in the sea. He even supposes that the abbé Nollet and M. Vianelli had found them. But he was satisfied that the sea is luminous chiefly on some other account, though he does not so much as advance a conjecture about what it is.

43
Experi-
ments by
M. Ant.
Martin.

M. Ant. Martin made many experiments on the light of fishes, with a view to discover the cause of the light of the sea. He thought that he had reason to conclude, from a great variety of experiments, that all
N° 182.

sea-fishes have this property; but that it is not to be found in any that are produced in fresh water. Nothing depended upon the colour of the fishes, except that he thought that the white ones, and especially those that had white scales, were a little more luminous than others. This light, he found, was increased by a small quantity of salt; and also by a small degree of warmth, though a greater degree extinguished it. This agrees with another observation of his, that it depends entirely upon a kind of moisture which they had about them, and which a small degree of heat would expel, when an oiliness remained which did not give this light, but would burn in the fire. Light from the flesh of birds or beasts is not so bright, he says, as that which proceeds from fish. Human bodies, he says, have sometimes emitted light about the time that they began to putrefy, and the walls and roof of a place in which dead bodies had often been exposed, had a kind of dew or clamminess upon it, which was sometimes luminous; and he imagined that the lights which are said to be seen in burying-grounds may be owing to this cause.

Light.
Sved.
Abhand.
vol. xxiii.
p. 235.

From some experiments made by Mr Canton, he concludes, that the luminousness of sea-water is owing to the slimy and other putrescent substances it contains. On the evening of the 14th of June 1768, he put a small fresh whiting into a gallon of sea-water, in a pan which was about 14 inches in diameter, and took notice that neither the whiting nor the water, when agitated, gave any light. A Fahrenheit's thermometer, in the cellar where the pan was placed, stood at 54°. The 15th, at night, that part of the fish which was even with the surface of the water was luminous, but the water itself was dark. He drew the end of a stick through it, from one side of the pan to the other; and the water appeared luminous behind the stick all the way, but gave light only where it was disturbed. When all the water was stirred, the whole became luminous, and appeared like milk, giving a considerable degree of light to the sides of the pan; and it continued to do so for some time after it was at rest. The water was most luminous when the fish had been in it about 28 hours; but would not give any light by being stirred, after it had been in it three days.

44
Canton.

He then put a gallon of fresh water into one pan, and an equal quantity of sea-water into another, and into each pan he put a fresh herring of about three ounces. The next night the whole surface of the sea-water was luminous, without being stirred; but it was much more so when it was put in motion; and the upper part of the herring, which was considerably below the surface of the water, was also very bright; while at the same time, the fresh water, and the fish that was in it, were quite dark. There were several very bright luminous spots on different parts of the surface of the sea-water; and the whole, when viewed by the light of a candle, seemed covered with a greasy scum. The third night, the light of the sea-water, while at rest, was very little, if at all, less than before; but when stirred, its light was so great as to discover the time by a watch, and the fish in it appeared as a dark substance. After this, its light was evidently decreasing, but was not quite gone before the 7th night.

The

Light.

The fresh water and the fish in it were perfectly dark during the whole time. The thermometer was generally above 60°.

The preceding experiments were made with sea-water; but he now made use of other water, into which he put common or sea-salt, till he found, by an hydrometer, that it was of the same specific gravity with the sea-water; and, at the same time, in another gallon of water, he dissolved two pounds of salt; and into each of these waters he put a small fresh herring. The next evening the whole surface of the artificial sea-water was luminous without being stirred; but gave much more light when it was disturbed. It appeared exactly like the real sea-water in the preceding experiment; its light lasted about the same time, and went off in the same manner: while the other water, which was almost as salt as it could be made, never gave any light. The herring which was taken out of it the seventh night, and washed from its salt, was found firm and sweet; but the other herring was very soft and putrid, much more so than that which had been kept as long in fresh water. If a herring, in warm weather, be put into 10 gallons of artificial sea-water, instead of one, the water, he says, will still become luminous, but its light will not be so strong.

It appeared by some of the first observations on this subject, that heat extinguishes the light of putrescent substances. Mr Canton also attended to this circumstance; and observes, that though the greatest summer heat is well known to promote putrefaction, yet 20 degrees more than that of the human blood seems to hinder it. For putting a small piece of a luminous fish into a thin glass ball, he found, that water of the heat of 118 degrees would extinguish its light in less than half a minute; but that, on taking it out of the water, it would begin to recover its light in about 10 seconds; but it was never afterwards so bright as before.

Mr Canton made the same observation that Mr Ant. Martin had done, viz. that several kinds of river fish could not be made to give light, in the same circumstances in which any sea-fish became luminous. He says, however, that a piece of carp made the water very luminous, though the outside, or scaly part of it, did not shine at all.

For the sake of those persons who may choose to repeat his experiments, he observes, that artificial sea-water may be made without the use of an hydrometer, by the proportion of four ounces avoirdupois of salt to seven pints of water, wine-measure.

From undoubted observations, however, it appears, that in many places of the ocean it is covered with luminous insects to a very considerable extent. Mr Dagelet, a French astronomer who returned from the Terra Australis in the year 1774, brought with him several kinds of worms which shine in water when it is set in motion; and M. Rigaud, in a paper inserted (if we are not mistaken) in the Journal des Scavans for the month of March 1770, affirms, that the luminous surface of the sea, from the port of Brest to the Antilles, contains an immense quantity of little, round, shining poly-

VOL. X. Part I.

puces of about a quarter of a line in diameter. Other learned men, who acknowledge the existence of these luminous animals, cannot, however, be persuaded to consider them as the cause of all that light and scintillation that appear on the surface of the ocean: they think that some substance of the phosphorus kind, arising from putrefaction, must be admitted as one of the causes of this phenomenon. M. Godehouse has published curious observations on a kind of fish called in French *bonite*, already mentioned; and though he has observed, and accurately described, several of the luminous insects that are found in sea-water, he is, nevertheless, of opinion, that the scintillation and flaming light of the sea proceed from the oily and greasy substances with which it is impregnated.

The abbé Nollet was long of opinion, that the light of the sea proceeded from electricity (A); though he afterwards seemed inclined to think, that this phenomenon was caused by small animals, either by their luminous aspect, or at least by some liquor or effluvia which they emitted. He did not, however, exclude other causes; among these, the spawn or fry of fish deserves to be noticed. M. Dagelet, sailing into the bay of Antongil, in the island of Madagascar, observed a prodigious quantity of fry, which covered the surface of the sea above a mile in length, and which he at first took for banks of sand on account of their colour; they exhaled a disagreeable odour, and the sea had appeared with uncommon splendor some days before. The same accurate observer, perceiving the sea remarkably luminous in the road of the Cape of Good Hope during a perfect calm, remarked, that the oars of the canoes produced a whitish and pearly kind of lustre; when he took in his hand the water which contained this phosphorus, he discerned in it, for some minutes, globules of light as large as the heads of pins. When he pressed these globules, they appeared to his touch like a soft and thin pulp; and some days after the sea was covered near the coasts with whole banks of these little fish in innumerable multitudes.

To putrefaction, also, some are willing to attribute that luminous appearance which goes by the name of *ignis fatuus*, to which the credulous vulgar ascribe very extraordinary and especially mischievous powers. It is most frequently observed in boggy places and near rivers, though sometimes also in dry places. By its appearance benighted travellers are said to have been sometimes misled into marshy places, taking the light which they saw before them for a candle at a distance; from which seemingly mischievous property it has been thought by the vulgar to be a spirit of a malignant nature, and been named accordingly *Will with a wisp*, or *Jack with a lantern*; for the same reason also it probably had its Latin name *ignis fatuus*.

This kind of light is said to be frequent about burying places and dung-hills. Some countries are also remarkable for it, as about Bologna in Italy, and some parts of Spain and Ethiopia. Its forms are so uncertain and variable that they can scarce be described, especially as few philosophical observers ever had the good fortune to meet with it. Dr Derham, however,

G

Ignis fatuus.

45
The ocean
luminous
from in-
sects.

(A) This hypothesis was also maintained in a treatise published at Venice in 1746, by an officer in the Austrian Service, under the title, *Deſt Elektriciſm*.

Light

happened one night to perceive one of them, and got so near that he could have a very advantageous view of it. This is by no means easy to be obtained; for, among other singularities of the *ignis fatuus*, it is observed to avoid the approach of any person, and fly from place to place as if it was animated. That which Dr Derham observed was in some boggy ground betwixt two rocky hills; and the night was dark and calm; by which means, probably, he was enabled to advance within two or three yards of it. It appeared like a complete body of light without any division, so that he was sure it could not be occasioned by insects as some have supposed; the separate lights of which he could not have failed to distinguish, had it been occasioned by them. The light kept dancing about a dead thistle, till a very slight motion of the air, occasioned, as he supposed, by his near approach to it, made it jump to another place; after which it kept flying before him as he advanced. M. Beccari endeavoured to procure all the intelligence he could concerning this phenomenon, by inquiring of all his acquaintance who might have had an opportunity of observing it. Thus he obtained information that two of these lights appeared in the plains about Bologna, the one to the north, and the other to the south, of that city, and were to be seen almost every dark night, especially that to the eastward, giving a light equal to an ordinary faggot. The latter appeared to a gentleman of his acquaintance as he was travelling; moved constantly before him for about a mile; and gave a better light than a torch which was carried before him. Both these appearances gave a very strong light, and were constantly in motion, though this was various and uncertain. Sometimes they would rise, sometimes sink; but commonly they would hover about six feet from the ground; they would also frequently disappear on a sudden, and appear again in some other place. They differed also in size and figure, sometimes spreading pretty wide, and then contracting themselves; sometimes breaking into two, and then joining again. Sometimes they would appear like waves, at others they would seem to drop sparks of fire: they were but little affected by the wind; and in wet and rainy weather were frequently observed to cast a stronger light than in dry weather: they were also observed more frequently when snow lay upon the ground, than in the hottest summer; but he was assured that there was not a dark night throughout the whole year in which they were not to be seen. The ground to the eastward of Bologna, where the largest of these appearances was observed, is a hard chalky soil mixed with clay, which will retain the moisture for a long time, but breaks and cracks in hot weather. On the mountains, where the soil is of a looser texture, and less capable of retaining moisture, the *ignis fatui* were less.

From the best information which M. Beccari was able to procure, he found that these lights were very frequent about rivers and brooks. He concludes his narrative with the following singular account. "An intelligent gentleman travelling in the evening, between eight and nine, in a mountainous road about ten miles south of Bologna, perceived a light which shone very strangely upon some stones which lay on the banks

of the river Rivoerde. It seemed to be about two feet above the stones, and not far from the water. In size and figure it had the appearance of a paralleloiped, somewhat more than a foot in length, and half a foot high, the longest side being parallel to the horizon. Its light was so strong, that he could plainly discern by it part of a neighbouring hedge and the water of the river; only in the east corner of it the light was rather faint, and the square figure less perfect, as if it was cut off or darkened by the segment of a circle. On examining it a little nearer, he was surprised to find that it changed gradually from a bright red, first to a yellowish, and then to a pale colour, in proportion as he drew nearer; and when he came to the place itself, it quite vanished. Upon this he stepped back, and not only saw it again, but found that the farther he went from it, the stronger and brighter it grew. When he examined the place of this luminous appearance, he could perceive no smell nor any other mark of fire." This account was confirmed by another gentleman, who informed M. Beccari, that he had seen the same light five or six different times in spring and in autumn; and that it always appeared of the same shape, and in the very same place. One night in particular, he observed it come out of a neighbouring field to settle in the usual place.

A very remarkable account of an *ignis fatuus* is given by Dr Shaw in his Travels to the Holy Land. It appeared in the valleys of mount Ephraim, and attended him and his company for more than an hour. Sometimes it would appear globular, or in the shape of the flame of a candle; at others it would spread to such a degree as to involve the whole company in a pale inoffensive light, then contract itself, and suddenly disappear; but in less than a minute would appear again; sometimes running swiftly along, it would expand itself at certain intervals over more than two or three acres of the adjacent mountains. The atmosphere from the beginning of the evening had been remarkably thick and hazy; and the dew, as they felt it on the bridles of their horses, was very clammy and unctuous.

Lights resembling the *ignis fatuus* are sometimes observed at sea, skipping about the masts and rigging of ships; and Dr Shaw informs us, that he has seen these in such weather as that just mentioned when he saw the *ignis fatuus* in Palestine. Similar appearances have been observed in various other situations; and we are told of one which appeared about the bed of a woman in Milan, surrounding it as well as her body entirely. This light fled from the hand which approached it; but was at length entirely dispersed by the motion of the air. Of the same kind also, most probably, are those small luminous appearances which sometimes appear in houses or near them, called in Scotland *Elf-candles*, and which are supposed to portend the death of some person about the house. In general these lights are harmless, though not always; for we have accounts of some luminous vapours which would encompass stacks of hay and corn, and set them on fire; so that they became objects of great terror and concern to the country people. Of these it was observed, that they would avoid a drawn sword, or sharp-pointed iron instrument, and that they would be driven away by a great noise; both which methods

Light

were made use of to dissipate them; and it was likewise observed, that they came from some distance, as it were on purpose to do mischief.

Several philosophers have endeavoured to account for these appearances, but hitherto with no great success; nor indeed does there seem to be sufficient data for solving all their phenomena. Willoughby, Ray, and others, have imagined that the light was occasioned by a number of shining insects; but this opinion was never supported in such a manner as to gain much ground. The *ignis fatuus* seen by Dr Derham above mentioned, as well as all the other instances we have related, seem to demonstrate the contrary. Sir Isaac Newton calls it a vapour shining without heat; and supposes that there is the same difference between the vapour of *ignis fatuus* and flame, that there is between the shining of rotten wood and burning coals. But though this seems generally to be the case, there are still some exceptions, as has been instanced in the vapours which set fire to the stacks of corn. Dr Priestley supposes that the light is of the same nature with that produced by putrescent substances; and others are of opinion, that the electrical fluid is principally concerned; but none have attempted to give any particular solution of the phenomena.

From the frequent appearance of the *ignis fatuus* in marshes, moist ground, burying places, and dung-hills, we are naturally led to conclude, that putrefaction is concerned in the production of it. This process, we know, is attended with the emission of an aqueous steam, together with a quantity of fixed, inflammable, phlogisticated, and alkaline airs, all blended together in one common vapour. It is likewise attended with some degree of heat; and we know that there are some vapours, that of sulphur particularly, which become luminous, with a degree of heat much less than that sufficient to set fire to combustible bodies. There is no inconsistency, therefore, in supposing that the putrid vapour may be capable of shining with a still smaller degree of heat than that of sulphur, and consequently become luminous by that which putrefaction alone affords. This would account for the *ignis fatuus*, were it only a steady luminous vapour arising from places where putrid matters are contained; but its extreme mobility, and flying from one place to another on the approach of any person, cannot be accounted for on this principle. If one quantity of the putrid vapour becomes luminous by means of heat, all the rest ought to do so likewise: so that though we may allow heat and putrefaction to be concerned, yet of necessity we must have recourse to some other agent, which cannot be any other than electricity. Without this it is impossible to conceive how any body of moveable vapour should not be carried away by the wind; but, so far is this from being the case, that the *ignis fatuus* described by M. Beccari were but little affected by the wind. It is besides proved by undoubted experiment, that electricity always is attended with some degree of heat; and this, however small, may be sufficient to give a luminous property to any vapour on which it acts strongly; not to mention, that the electric fluid itself is no other than that of light, and may therefore by its action easily produce a luminous appearance independent of any vapour.

We have a strong proof that electricity is concerned, or indeed the principal agent, in producing the *ignis fatuus* from an experiment related by Dr Priestley of a flame of this kind being artificially produced. A gentleman, who had been making many electrical experiments for a whole afternoon in a small room, on going out of it, observed a flame following him at some little distance. This, we have no reason to doubt, was a true *ignis fatuus*, and the circumstances necessary to produce it were then present, viz. an atmosphere impregnated with animal vapour, and likewise strongly electrified. Both these circumstances undoubtedly must have taken place in the present case; for the quantity of perspiration emitted by a human body is by no means inconsiderable; and it as well as the electricity would be collected by reason of the smallness of the room. In this case, however, there seems to have been a considerable difference between the artificial *ignis fatuus* and those commonly met with; for this flame followed the gentleman as he went out of the room; but the natural ones commonly fly from those who approach them. This may be accounted for, from a difference between the electricity of the atmosphere in the one room and the other; in which case the flame would naturally be attracted towards that place where the electricity was either different in quality or in quantity; but in the natural way, where all bodies may be supposed equally electrified for a great way round, a repulsion will as naturally take place. Still, however, this does not seem to be always the case. In those instances where travellers have been attended by an *ignis fatuus*, we cannot suppose it to have been influenced by any other power than what we call attraction, and which electricity is very capable of producing. Its keeping at some distance is likewise easily accounted for; as we know that bodies possessed of different quantities of electricity may be made to attract one another for a certain space, and then repel without having ever come into contact. On this principle we may account for the light which surrounded the woman at Milan, but fled from the hand of any other person. On the same principle may we account for these mischievous vapours which set fire to the hay and corn stacks, but were driven away by presenting to them a pointed iron instrument, or by making a noise. Both these are known to have a great effect upon the electric matter; and by means of either, even lightning may occasionally be made to fall upon or to avoid particular places, according to the circumstances by which the general mass happens to be affected at that time.

On the whole, therefore, it seems most probable, that the *ignis fatuus* is a collection of vapour of the putrescent kind, very much affected by electricity; according to the degree of which, it will either give a weak or strong light, or even set fire to certain substances disposed to receive its operation. This opinion seems greatly to be confirmed from some luminous appearances observed in privies, where the putrid vapours have even collected themselves into balls, and exploded violently on the approach of a candle. This last effect, however, we cannot so well ascribe to the electricity, as to the accession of the inflammable air which frequently abounds in such places.

Light.

experiments and observations on air, Mr Warrtine gives an account of some very remarkable *ignes fatui*, which he observed on the road to Bromgrove, about five miles from Birmingham. The time of observation was the 12th of December 1776, before day-light. A great many of these lights were playing in an adjacent field, in different directions; from some of which there suddenly sprang up bright branches of light, something resembling the explosion of a rocket that contained many brilliant stars, if the discharge was upwards, instead of the usual direction, and the hedge and trees on each side of the hedge were illuminated. This appearance continued but a few seconds, and then the jack-a-lanterns played as before. Mr Warrtine was not near enough to observe if the apparent explosions were attended with any report.

Cronstedt gives it as his opinion, that *ignes fatui*, as well as the meteors called *falling stars*, are owing to collections of inflammable air raised to a great height in the atmosphere. But, with regard to the latter, the vast height at which they move evidently shows that they cannot be the effect of any *gravitating* vapour whatever; for the lightest inflammable air is one-twelfth of that of the common atmosphere: and we have no reason to believe, that at the distance of 40 or 50 miles from the earth, the latter has near $\frac{1}{12}$ of its weight at the surface. From the account given by Mr Warrtine, we should be apt to conclude, that there is a strong affinity betwixt the *ignes fatui* and fire-balls, inasmuch that the one might be very easily converted into the other. From this then we must ascribe an electrical origin to the one as well as the other. Electricity, we know, can assume both these appearances, as is evident in the case of points; or even when the atmosphere is violently electrified, as around the string of an electrical kite, which always will appear to be surrounded with a blue flame in the night, if the electricity be very strong.

On the whole, it appears, that electricity acting upon a small quantity of atmospheric air, with a certain degree of vigour, will produce an appearance resembling an *ignes fatui*; with a superior force it will produce a fire-ball; and a sudden increase of electrical power might produce those sparks and apparent explosions observed by Mr Warrtine. The only difficulty therefore is, Why does electricity exert its power upon one portion of the atmosphere rather than another, seeing it has an opportunity of diffusing itself equally through the whole? To this it seems impossible to give any other reason than that we see the fact is so; and that in all cases where there is a quantity of electrified air or vapour, there will be an accumulation in one part rather than another. Thus, in the experiment already related, where the gentleman perceived a blue flame following him, the whole air of the room was electrified, but the greatest power of the fluid was exerted on that which gave the luminous appearance.

With regard to the uses of the *ignes fatui* in the system of nature, we can only say, that they seem to be accidental appearances resulting from the motion of the electric fluid, and are, no doubt, like other meteors, subservient to the preservation of its equilibrium, and thus are useful in preventing those dreadful commotions which ensue when a proper medium for so doing is deficient.

Light.

A light in some respects similar to those above mentioned has been found to proceed from that celebrated chemical production called *phosphorus*, which always tends to decompose itself, so as to take fire by the access of air only. Phosphorus, therefore, when it emits light, is properly a body ignited; though when a very small quantity of it is used, as what is left after drawing it over paper, or what may be dissolved in essential oil, the heat is not sensible. But perhaps the matter which emits the light in what we call *putrescent substances* may be similar to it, though it be generated by a different process, and burn with a less degree of heat. Putrefaction does not seem to be necessary to the light of glow-worms, or of the pholades; and yet their light is sufficiently similar to that of shining wood or flesh. Electric light is unquestionably similar to that of phosphorus, though the source of it is apparently very different.

Kunkel formed his phosphorus into a kind of pills about the size of peas, which being moistened a little, and scraped in the dark, yielded a very considerable light, but not without smoke. The light was much more pleasing when eight or ten of these pills were put into a glass of water; for being shaken in the dark, the whole glass seemed to be filled with light. Kunkel also reduced his phosphorus into the form of larger stones; which being warmed by a person's hand, and rubbed upon paper, would describe letters that were very legible in the dark.

The greatest variety of experiments with the light of phosphorus was made by Dr Slare; who says, that the liquid phosphorus (which is nothing more than the solid phosphorus dissolved in any of the essential oils) would not hurt even a lady's hand; or that, when the hands or face were washed with it, it would not only make them visible to other persons in the dark, but that the light was so considerable as to make other neighbouring objects visible.

When the solid phosphorus is quite immersed in water, he observes that it ceases to shine; but that if any part of it chance to emerge, or get into the air, it will shine though the glass be hermetically sealed. In a large glass he kept it without water for several days; and yet it continued shining, with very little diminution of its light or weight. If the letters that were written with this phosphorus were warmed by the fire, they presently became dark lines, which continued upon the paper, like ink. To try how much light was given by a small quantity of this phosphorus, he observed that it continued to flame in the open air for seven or eight days; the light being visible whenever he shut his window.

As air was generally thought to contain the *pabulum* of flame, Dr Slare was determined to try this with respect to phosphorus; and for this purpose he placed a large piece of it in a receiver; but upon exhausting it, he perceived that it became more luminous, and that, upon admitting the air, it returned to its former state. This property of the light of phosphorus, which is the very reverse of that of shining wood and fishes, was also ascertained by several very accurate experiments of Mr Hauksbee's.

Endeavouring to blow the phosphorus into a flame with a pair of bellows, Dr Slare found that it was presently blown out, and that it was a considerable time before

47
phosphoric
light

Light.

before the light revived again. All liquors would extinguish this light when the phosphorus was put into them; nor would it shine or burn, though it was even boiled in the most inflammable liquors, as oil of olives, spirit of turpentine, or even spirit of wine.

In order to keep his phosphorus from confuming, he used to put it in a glass of water; and sometimes he has seen it, when thus immersed in water, make such bright and vigorous conflagrations in the air, as, he says, would surprise and frighten those who are not used to the phenomenon. This fiery meteor, he says, is contracted in its passage through the water, but expands as soon as it gets above it. If any person would make this experiment to advantage, he informs them that the glass must be deep and cylindrical, and not above three quarters filled with water. This effect he perceived in warm weather only, and never in cold.

The phosphorus of which we have been treating is prepared from urine; but in some cases the sweat, which is similar to urine, has been observed to be phosphoreous, without any preparation. This once happened to a person who used to eat great quantities of salt, and who was a little subject to the gout, after sweating with violent exercise. Stripping himself in the dark, his shirt seemed to be all on fire, which surprised him very much. Upon examination, red spots were found upon his shirt; and the physician who was present perceived an urinous smell, though it had nothing in it of volatile alkali, but of the muriatic acid; the same, he says, that issues from cabbage much salted, and strongly fermented.

The easiest method of accounting for all these kinds of lights, perhaps, is from electricity. If light consists in a certain vibration of the electric fluid†, then it follows, that in whatever substances such a vibration takes place, there light must appear, whether in putrescent animal substances, sea-water, phosphorus, or any thing else. We know that the electric matter pervades all terrestrial substances, and is very liable to be set in motion from causes of which we are ignorant. The action of the air by which putrefaction is produced may be one of these causes; and it can by no means appear surprising that the electric matter should act in the bodies of living animals in such a manner as to produce a permanent light, when we certainly know it acts in some of them so powerfully as to produce a shock similar to that of a charged vial.—On this subject we shall only observe farther, that when this vibration becomes so powerful as to penetrate the solid substance of the body itself, the luminous body then becomes transparent, as in the milk mentioned in the former part of this article; but, when it is only superficial, the body, though it emits light, is itself opaque.

Light from Diamonds. Among luminous bodies the diamond is to be reckoned; as some diamonds are known to shine in the dark. But on account of the feebleness of their splendor, it is necessary for the person who is to observe them, previously to stay in the dark at least a quarter of an hour; that the pupil of the eye may be dilated and enlarged, and so rendered capable of receiving a larger quantity of the rays of light. M. du Fay has also observed, that the eyes ought to be shut for this time, or at least one of them; and that, in that case, the light of the diamond is afterwards only seen by that eye which has been shut. Before the diamond is

Light.

brought into the dark room, it must be exposed to the sun-shine, or at least to the open day-light, to imbibe a sufficient quantity of rays; and this is done in one minute, or even less; eight or ten seconds having been found to furnish as much light as a stone is capable of receiving; and when brought into the dark, its light continues about twelve or thirteen minutes, weakening all the while by insensible degrees. It is very remarkable, that in bodies so extremely similar to each other as diamonds are, some should have this property of imbibing the sun's rays, and shining in the dark, and that others should not; yet so it is found to be by experiment, and the most nearly resembling stones shall be found one to have this property, and another to be destitute of it; while many of the most dissimilar have the property in common. There seems to be no rule, nor even the least traces of any imperfect rule of judging, which diamonds have, and which have not this property; their natural brightness, their purity, their size, or their shape, contribute nothing to it; and all that has been yet discovered of the least regularity among them, is, that all the yellow diamonds have this property. This may probably arise from their having more sulphur in their composition, and therefore illuminating more readily, or emitting a more visible flame.

The burning of diamonds is a term used among the jewellers, for putting them into a fierce fire, as they frequently do, when they are fouled with brown, or yellow, or the like; this always divests them of their colour, without doing them the least sensible injury. M. du Fay, having been informed of this common practice, formed a conjecture, that the difference of diamonds in their shining, or not shining in the dark, was owing to it; and that either all those which had been burnt, or all those which had not, were those which alone shone in the dark. But this was found an erroneous conjecture; for two diamonds, one lucid in the dark, the other not, were both burnt, and afterwards both were found to retain the same properties they had before. It is not only the open sunshine, or open day-light, which gives to these diamonds the power of shining in the dark; they receive it in the same manner, even if laid under a glass, or plunged in water or in milk.

M. du Fay tried whether it was possible to make the diamond retain, for any longer time, the light it naturally parts with so soon; and found, that if the diamond, after being exposed to the light, be covered with black wax, it will shine in the dark, as well six hours afterwards as at the time it was first impregnated with the light.

The imbibing light, in this manner, being so nice a property as it is to be found in several diamonds, it was not to be supposed that it would be found in any other stones: accordingly, on trial, the ruby, the sapphire, and the topaz, were found wholly destitute of it; and among a large number of rough emeralds, one only was found to possess it. Such is the strange uncertainty of these accidents.

All the other less precious stones were tried, and found not to possess this property of imbibing light from the day-light or sun-shine, but they all became luminous by the different means of heating or friction; with this difference, that some acquired it by one of these.

tricity.

Light.

these methods, and others by the other; each being unaffected by that which gave the property to the other. The diamond becomes luminous by all these ways.

Beccarius also discovered, that diamonds have the property of the Bolognian phosphorus, about the same time that it occurred to M. du Fay. *Com. Bonon.* vol. ii. p. 276. M. du Fay likewise observed, that the common topaz, when calcined, had all the properties of this phosphorus; and pursuing the discovery, he found the same property, in a great degree, in the belemnites, gypsum, lime-stone, and marble: though he was obliged to dissolve some very hard substances of this kind in acids, before calcination could produce this change in them; and with some substances he could not succeed even thus; especially with flint-stones, river-sand, jaspers, agates, and rock-crystal.

LIGHT from Plants. In Sweden a very curious phenomenon has been observed on certain flowers by M. Haggren, lecturer in natural history. One evening he perceived a faint flash of light repeatedly dart from a marigold. Surprised at such an uncommon appearance, he resolved to examine it with attention; and, to be assured it was no deception of the eye, he placed a man near him, with orders to make a signal at the moment when he observed the light. They both saw it constantly at the same moment.

The light was most brilliant on marigolds of an orange or flame colour; but scarcely visible on pale ones.

The flash was frequently seen on the same flower two or three times in quick succession; but more commonly at intervals of several minutes: and when several flowers in the same place emitted their light together, it could be observed at a considerable distance.

This phenomenon was remarked in the months of July and August at sun-set, and for half an hour, when the atmosphere was clear; but after a rainy day, or when the air was loaded with vapours, nothing of it was seen.

The following flowers emitted flashes, more or less vivid, in this order:

1. The marigold, *galendula officinalis*.
2. Monk's-hood, *tropæolum majus*.
3. The orange-lily, *lilium bulbiferum*.
4. The Indian pink, *tagetes potula* & *erecta*.

To discover whether some little insects or phosphoric worms might not be the cause of it, the flowers were carefully examined, even with a microscope, without any such being found.

From the rapidity of the flash, and other circumstances, it may be conjectured that there is something of electricity in this phenomenon. It is well known, that when the pistil of a flower is impregnated, the pollen bursts away by its elasticity, with which electricity may be combined. But M. Haggren, after having observed the flash from the orange lily, the anthers of which are a considerable space distant from the petals, found that the light proceeded from the petals only; whence he concludes, that this electric light is caused by the pollen, which, in flying off, is scattered on the petals. Whatever be the cause, the effect is singular and highly curious.

LIGHTS, in painting, are those parts of a piece which are illuminated, or that lie open to the luminary,

by which the piece is supposed to be enlightened; and which, for this reason, are painted in bright vivid colours.

Light
||
Lightfoot.

In this sense, light is opposed to shadow.

Different lights have very different effects on a picture, and occasion a difference in the management of every part. A great deal therefore depends on the painter's choosing a proper light for his piece to be illuminated by; and a great deal more, in the conduct of the lights and shadows, when the luminary is pitched upon.

The strength and relief of a figure, as well as its gratefulness, depend entirely on the management of the lights, and the joining of those to the shadows.

The light a figure receives is either direct or reflected; to each of which special regard must be had. The doctrine of lights and shadows makes that part of painting called *châsse d'œuvre*.

LIGHT-HORSE, an ancient term in our English customs, signifying an ordinary cavalier or horseman lightly armed, and so as to enter a corps or regiment; in opposition to the men at arms, who were heavily accoutred, and armed at all points. See *Light-Horses*.

LIGHT-HOUSE, a building erected upon a cape or promontory on the sea-coast, or upon some rock in the sea, and having on its top in the night-time a great fire, or light formed by candles, which is constantly attended by some careful person, so as to be seen at a great distance from the land. It is used to direct the shipping on the coast, that might otherwise run ashore, or steer an improper course when the darkness of the night and the uncertainty of currents, &c. might render their situation with regard to the shore extremely doubtful. Lamp-lights are, on many occasions, preferable to coal-fires or candles; and the effect of these may be increased by placing them either behind glass-hemispheres, or before properly disposed glass or metal reflectors, which last method is now very generally adopted. See *BEACONS*.

LIGHT-ROOM, a small apartment, inclosed with glass-windows, near the magazine of a ship of war. It is used to contain the lights by which the gunner and his assistants are enabled to fill cartridges with powder to be ready for action.

LIGHTER, a large, open, flat-bottomed vessel, generally managed with oars, and employed to carry goods to or from a ship when he is to be laden or delivered.—There are also some lighters furnished with a deck throughout their whole length, in order to contain those merchandises which would be damaged by rainy weather: these are usually called *close lighters*.

LIGHTFOOT (John), a most learned English divine, was the son of a divine, and born in March 1602, at Stoke upon Trent in Staffordshire. After having finished his studies at a school on Morton-green near Congleton in Cheshire, he was removed in 1617 to Cambridge, where he applied himself to eloquence, and succeeded so well in it as to be thought the best orator of the under-graduates in the university. He also made an extraordinary proficiency in the Latin and Greek; but neglected the Hebrew, and even lost that knowledge he brought of it from school. His taste for the oriental languages was not yet excited; and as for logic, the study of it, as managed at that time among the academics, was too quarrelsome and fierce

fiere for his quiet and meek disposition. As soon as he had taken the degree of B. A. he left the university, and became assitant to a school at Repton in Derbyshire. After he had supplied this place a year or two, he entered into orders, and became curate of Norton under Hailes in Shropshire. This curacy gave an occasion of awakening his genius for the Hebrew tongue. Norton lies near Bellaport, then the seat of Sir Rowland Cotton; who was his constant hearer, made him his chaplain, and took him into his house. This gentleman being a perfect master of the Hebrew language, engaged Lightfoot in that study; who, by conversing with his patron, soon became sensible that without that knowledge it was impossible to attain an accurate understanding of the scriptures. He therefore applied himself to it with extraordinary vigour, and in a little time made a great progress in it: and his patron removing with his family to reside in London, at the request of Sir Alland Cotton his uncle, who was lord-mayor of that city, he followed his preceptor thither. But he did not stay long there: for, having a mind to improve himself by travelling abroad, he went down into Staffordshire to take leave of his father and mother. Passing through Stone in that county, he found the place destitute of a minister: and the pressing instances of the parishioners prevailed upon him to undertake that cure. Hereupon, laying aside his design of travelling abroad, he began to turn his thoughts upon settling at home. During his residence at Bellaport, he had fallen into the acquaintance of a gentleman who was daughter of William Crompton of Stonepark, Esq; and now, being in possession of that living, he married her in 1628. But notwithstanding this settlement, his unquenchable thirst after rabbinical learning would not suffer him to continue there. Sion-college library at London, he knew, was well stocked with books of that kind. He therefore quitted his charge at Stone, and removed with his family to Hornsey, near the city; where he gave the public a notable specimen of his advancement in those studies, by his "Erubhim, or Miscellanies Christian and Judaical," in 1629. He was at this time only 27 years of age; and appears to have been well acquainted with the Latin and the Greek fathers, as well as the ancient heathen writers. These first fruits of his studies were dedicated to Sir Rowland Cotton; who, in 1631, presented him to the rectory of Ashley in Staffordshire.

He seemed now to be fixed for life: Accordingly, he built a study in the garden, to be out of the noise of the house; and applied himself with indefatigable diligence in searching the scriptures. Thus employed, the days passed very agreeably; and he continued quiet and unmolested, till the great change which happened in the public affairs brought him into a share of the administration relating to the church; for he was nominated a member of the memorable assembly of divines for settling a new form of ecclesiastical polity. This appointment was purely the effect of his distinguished merit; and he accepted it purely with a view to serve his country, as far as lay in his power. The non-residence, which this would necessarily occasion, apparently induced him to resign his rectory: and having obtained the presentation for a younger brother, he set out for London in 1642. He had now

satisfied himself in clearing up many of the abstrusest passages in the Bible, and therein had provided the chief materials, as well as formed the plan, of his "Harmony;" and an opportunity of inspecting it at the press was, no doubt, an additional motive for his going to the capital; where he had not been long before he was chosen minister of St Bartholomew's, behind the Royal Exchange. The assembly of divines meeting in 1643, our author gave his attendance diligently there, and made a distinguished figure in their debates; where he used great freedom, and gave signal proofs of his courage as well as learning, in opposing many of those tenets which the divines were endeavouring to establish. His learning recommended him to the parliament, whose visitors, having ejected Dr William Spurstow from the mastership of Catharine-hall in Cambridge, put Lightfoot in his room, this year 1653; and he was also presented to the living of Much-Munden in Hertfordshire, void by the death of Dr Samuel Ward, Margaret-professor of divinity in that university, before the expiration of this year. Meanwhile he had his turn with other favourites in preaching before the house of commons, most of which sermons were printed; and in them we see him warmly pressing the speedy settlement of the church in the Presbyterian form, which he cordially believed to be according to the pattern in the Mount. He was all the while employed in preparing and publishing the several branches of his Harmony; all which were so many excellent specimens of the usefulness of human learning to true religion; and he met with great difficulties and discouragements in that work, chiefly from that antirenditional spirit which prevailed, and even threatened the destruction of the universities. In 1655 he entered upon the office of vice-chancellor of Cambridge, to which he was chosen that year, having taken the degree of doctor of divinity in 1652. He performed all the regular exercises for his degree with great applause, and executed the vice-chancellor's office with exemplary diligence and fidelity; and, particularly at the commencement, supplied the place of professor of divinity, then undisposed of, as an act which was kept for a doctor's degree in that profession. At the same time he was engaged with others in perfecting the Polyglott Bible, then in the press. At the Restoration he offered to resign the mastership of Catharine-hall: But, as what he had done had been rather in compliance with the necessity of the times, than from any zeal or spirit of opposition to the king and government, a confirmation was granted him from the crown, both of the place and of his living. Soon after this he was appointed one of the assistants at the conference upon the liturgy, which was held in the beginning of 1661, but attended only once or twice; probably disgusted at the heat with which that conference was managed. However, he stuck close to his design of perfecting his Harmony: and being of a strong and healthy constitution, which was assisted by an exact temperance, he prosecuted his studies with unabated vigour to the last, and continued to publish, notwithstanding the many difficulties he met with from the expense of it. However, not long before he died, some booksellers got a promise from him to collect and methodize his works, in order to print them; but the execution was prevented by his death, which happened Dec. 6. 1675. The doctor was twice married: his

first.

Lightning. first wife, already mentioned, brought him four sons and two daughters. His second wife was likewise a widow, and relict of Mr Austin Brograve, uncle of Sir Thomas Brograve, Bart. of Hertfordshire, a gentleman well versed in rabbinical learning, and a particular acquaintance of our author. He had no issue by her. She also died before him, and was buried in Munden church; where the doctor was himself likewise interred near both his wives. Dr Lightfoot's works were collected and published first in 1684, in two volumes folio. The second edition was printed at Amsterdam, 1686, in two volumes folio, containing all his Latin writings, with a Latin translation of those which he wrote in English. At the end of both these editions there is a list of such pieces as he left unfinished. It is the chief of these, in Latin, which make up the third volume, added to the former two, in a third edition of his works, by John Leusden, at Utrecht, in 1699, fol. They were communicated by Mr Strype, who, in 1700, published another collection of these papers, under the title of "Some genuine remains of the late pious and learned Dr John Lightfoot."

LIGHTNING, a bright and vivid flash of fire, suddenly appearing in the atmosphere, and commonly disappearing in an instant, sometimes attended with clouds and thunders, and sometimes not.

The phenomena of lightning are always surprising, and sometimes very terrible; neither is there any kind of natural appearance in which there is more diversity, not two flashes being ever observed exactly similar to one another. In a serene sky, the lightning, in this country at least, almost always hath a kind of indistinct appearance without any determinate form, like the sudden illumination of the atmosphere occasioned by firing a quantity of loose gunpowder; but when accompanied with thunder, it is well defined, and hath very often a zig-zag form. Sometimes it makes only one angle, like the letter V, sometimes it hath several branches, and sometimes it appears like the arch of a circle. But the most formidable and destructive form which lightning is ever known to assume is that of balls of fire. The motion of these is very often easily perceptible to the eye; but wherever they fall, much mischief is occasioned by their bursting, which they always do with a sudden explosion like that of fire-arms. Sometimes they will quietly run along, or rest for a little upon any thing, and then break into several pieces, each of which will explode; or the whole ball will burst at once, and produce its mischievous effects only in one place. The next to this in its destructive effects is the zig-zag kind; for that which appears like indistinct flashes, whose form cannot be readily observed, is seldom or never known to do hurt.—The colour of the lightning also indicates in some measure its power to do mischief; the palest and brightest flashes being most destructive; such as are red, or of a darker colour, commonly doing less damage.

A very surprising property of lightning, the zig-zag kind especially when near, is its seeming omnipresence. If two persons are standing in a room looking different ways, and a loud clap of thunder accompanied with zig-zag lightning happens, they will both distinctly see the flash, not only by that indi-

distinct illumination of the atmosphere which is occasioned by fire of any kind; but the very form of the lightning itself, and every angle it makes in its course, will be as distinctly perceptible, as though they had looked directly at the cloud from whence it proceeded. If a person happened at that time to be looking on a book, or other object which he held in his hand, he would distinctly see the form of the lightning between him and the object at which he looked. This property seems peculiar to lightning, and to belong to no other kind of fire whatever.

The effects of lightning are generally confined within a small space; and are seldom similar to those which accompany explosions of gun-powder, or of inflammable air in mines. Instances of this kind, however, have occurred; the following is one of the most remarkable of which we have any distinct account. "August 2. 1763, about six in the evening, there arose at Anderlight, about a league from Brussels, a conflict of several winds borne upon a thick fog. This conflict lasted four or five minutes, and was attended with a frightful hissing noise, which could be compared to nothing but the yellings of an infinite number of wild beasts. The cloud then opening, discovered a kind of very bright lightning, and in an instant the roofs of one side of the houses were carried off and dispersed at a distance; above 1000 large trees were broke off, some near the ground, others near the top, some torn up by the roots; and many both of the branches and tops carried to the distance of 60, 100, or 120 paces; whole coppices were laid on one side, as corn is by ordinary winds. The glass of the windows which were most exposed was shivered to pieces. A tent in a gentleman's garden was carried to the distance of 4000 paces; and a branch torn from a large tree, struck a girl in the forehead as she was coming into town, at the distance of 40 paces from the trunk of the tree, and killed her on the spot."

These terrible effects seem to have been owing to the prodigious agitation in the air, occasioned by the emission of such a vast quantity of lightning at once; or perhaps to the agitation of the electric fluid itself, which is still more dangerous than any concussion of the atmosphere; for thunder-storms will sometimes produce most violent whirlwinds, such as are by the best philosophers attributed to electricity, nay, even occasion an agitation of the waters of the ocean itself; and all this too after the thunder and lightning had ceased.—Of this we have the following instances. "Great Malvern, October 16. 1761. On Wednesday last, we had the most violent thunder ever known in the memory of man. At a quarter past four in the afternoon I was surprised with a most shocking and dismal noise; 100 forges (the nearest resemblance I can think of), were they all at work at once, could scarce equal it. I ran to the fore-door, and casting my eye upon the side of the hill about 400 yards to the south-west of my house, there appeared a prodigious smoke, attended with the same violent noise. I ran back into the house, and cried out, a volcano (for so I thought) had burst out of the hill; but I had no sooner got back again, than I found it had descended, and was passing on within about 100 yards of the south end of my house. It seemed to rise again in the meadow just below it; and

Lightning. continued its progress to the east, rising in the same manner for four different times, attended with the same dismal noise as at first; the air being filled with a nauseous and sulphureous smell. I saw it gradually decrease till quite extinguished in a turnip-field about a quarter of a mile below my house. The turnip leaves, with leaves of trees, dirt, sticks, &c. filled the air, and flew higher than any of these hills. The thunder ceased before this happened, and the air soon afterwards became calm and serene."—The vast column of smoke mentioned in the above letter was so large, that a physician of eminence at Worcester saw it in its progress down the hill, about a mile from Fecckenham, which is above 20 miles from Malvern.—In August 1763, a most violent storm of thunder, rain, and hail, happened at London, which did damage in the adjacent country, to the amount of 50,000*l*. Hailstones fell of an immense size, from two to ten inches circumference; but the most surprising circumstance was the sudden flux and reflux of the tide in Plymouth pool, exactly corresponding with the like agitation in the same place, at the time of the great earthquake at Lisbon.

Instances are also to be found, where lightning, by its own proper force, without any assistance from those less common agitations of the atmosphere or electric fluid, hath thrown stones of immense weight to considerable distances; torn up trees by the root, and broke them in pieces; shattered rocks; beat down houses, and set them on fire, &c.

Extraordinary effects of lightning upon a pyed bullock. A very singular effect of lightning is mentioned in the 66th volume of the Philosophical Transactions, upon a pyed bullock. It happened in the county of Suffolk about the end of August 1774. The bullock was white and red; and the lightning stripped off the white hair leaving the red untouched. The following is a particular account of the matter. "In the evening of Sunday, the 28th of August, there was an appearance of a thunder-storm, but we heard no report. A gentleman who was riding near the marshes not far distant from this town (Lewes) saw two strong flashes of lightning, seemingly running along the ground of the marsh, at about nine o'clock in the evening. On Monday morning, when the servants of Mr Roger, a farmer at Swanborough, in the parish of Iford, went into the marsh to fetch the oxen to their work, they found one of them, a four-year-old steer, standing up to appearance much burnt, and so weak as to be scarce able to walk. The animal seemed to have been struck by lightning in a very extraordinary manner. He is of a white and red colour; the white in large marks, beginning at the rump bone, and running in various directions along both the sides; the belly is all white, and the whole head and horns white likewise. The lightning, with which he must have been undoubtedly struck, fell upon the rump bone, which is white, and distributed itself along the sides in such a manner as to take off all the hair from the white marks as low as the bottom of the ribs, but so as to leave a list of white hair, about half an inch broad, all round where it joined to the red, and not a single hair of the red appears to be touched. The whole belly is unhurt, but the end of the sheath of the penis has the hair taken off; it is also taken off from the dewlap: the horns and the curled hair on the forehead are uninjured; but

the hair is taken off from the sides of the face, from the flat part of the jaw-bones, and from the front of the face in stripes. There are a few white marks on the side and neck, which are surrounded with red; and the hair is taken off from them, leaving half an inch of white adjoining to the red. The farmer anointed the ox with oil for a fortnight; the animal purged very much at first, and was greatly reduced in flesh, but is now recovering."

In another account of this accident, the author supposes that the bullock had been lying down at the time he was struck; which shows the reason that the under parts were not touched. "The lightning, conducted by the white hair, from the top of the back down the sides, came to the ground at the place where the white hair was left entire."

The author of this account says, that he inquired of a Mr Tooth a farmer, whether he ever knew of a similar accident; and that he told him "the circumstance was not new to him; that he had seen a great many pyed bullocks struck by lightning in the same manner as this; that the texture of the skin under the white hair was always destroyed, though looking fair at first; but after a while it became sore, throwing out a putrid matter in pustules, like the small-pox with us, which in time falls off, when the hair grows again, and the bullocks receive no farther injury;" which was the case with the bullock in question. In a subsequent letter, however, the very same author informs us, that he had inquired of Mr Tooth "whether he ever saw a stroke of lightning actually fall upon a pyed bullock, so as to destroy the white hair, and show evident marks of burning, leaving the red hair uninjured? He said he never did; nor did he recollect any one that had. He gave an account, however, of a pyed horse, belonging to himself, which had been struck dead by lightning in the night-time." The explosion was so violent, that Mr Tooth imagined his house had been struck, and therefore immediately got up. On going into the stable he found the horse almost dead to appearance, though it kept on its legs near half an hour before it expired. The horse was pyed white on the shoulder and greatest part of the head; viz. the forehead and nose, where the greatest force of the stroke came. "The hair was not burnt nor discoloured, only so loosened at the root, that it came off with the least touch. And this is the case, according to Mr Tooth's observation, with all that he has seen or heard of; viz. the hair is never burnt, but the skin always affected as above mentioned. In the horse, all the blood in the veins under the white parts of the head was quite stagnated, though he could perceive it to flow in other parts as usual; and the skin, together with one side of the tongue, was parched and dried up to a greater degree than he had ever seen before."

Another instance is mentioned of this extraordinary effect of lightning upon a bullock, in which even the small red spots on the sides were unaffected; and in this, as well as the former, the white hair on the under part of the belly, and on the legs, was left untouched.

All these, however, are to be considered as the more unusual phenomena of lightning; its common mode of action being entirely similar to that of a charged Leyden vial, where the electric matter discharges

Lightning.

itself from a substance positively electrified to one that is negatively so. The identity of electric matter and lightning seems now, indeed, to be well established, that there is not the least foundation for seeking any other solution of the phenomena of lightning, than what may be obtained by comparing them with those of our electrical experiments. The different forms of the flashes are all exemplified in those of electrical sparks. Where the quantity of electricity is small, and consequently incapable of striking at any considerable distance, the spark appears straight, without any curvature or angular appearance: but where the electricity is very strong, and of consequence capable of striking an object at a pretty considerable distance, it assumes a crooked or zig-zag form. This is always the case with Mr Nairn's very powerful machines, the conductors of which are six feet in length and one foot in diameter. Sparks may be taken from them at the distance of 16, 17, or even 20 inches; and all of these put on the angular zig-zag form of lightning.

Why it assumes a zig-zag form.

The reason of this appearance, both in these sparks and in the lightning, is, that the more fluid electric matter hath to pass through the denser and less fluid atmosphere with great rapidity; and in fact, this is the way in which all the more fluid substances pass through those that are less so, at least when their velocity becomes considerable. If bubbles of air or steam pass very gently up through water, their course from the bottom to the top of the vessel will differ very little, if at all, from a straight line; but when they are impelled by a considerable force, as in air blown from a bellows, or the bubbles of steam which arise in boiling water, their course is then marked by waved and crooked lines, and the deflection of the bubbles to the right or left will be precisely in proportion to their ascending velocity, and to the weight of the water by which they are resisted.

In the case of air blown through water, however, or steam ascending from the bottom of a vessel of boiling water, though the course of the bubbles is waved and crooked, we never observe it to be angular as in lightning. The reason of this is, that there is no proportion between the capacity of the air for yielding to the impetus of lightning, and the velocity with which the latter is moved. From Mr Robins's experiments in gunnery, it appears, that the air cannot yield with a velocity much greater than 1200 feet in a second, and that all projectiles moving with a greater degree of velocity meet with a violent resistance. But if we suppose lightning to move only with one half the velocity of light, that is, near 100,000 miles in a second, or even with that of 1000 miles in a minute, which most probably is the case*, its motion in the fluid atmosphere will meet with a resistance very little inferior to what air would meet with in passing through the most solid bodies. The smallest difference of the resistance of the atmosphere on either side, must determine the lightning to that side; and in its passage to that new place where the resistance is less, it must pass on in a straight line, making an angle with its former course, because the atmosphere is altogether incapable of yielding with such rapidity as the electric matter requires, and therefore resists like a solid rock. 'The case is otherwise in the former examples: for tho' a small difference in the resistance forces the bubbles of

* See Fireball.

air or steam to deviate from side to side, yet there is always a considerable proportion between the capacity of water for yielding, and that force by which the bubbles urge it to yield; so that though it does make a resistance sufficient to prevent the bubbles from moving in a straight line, yet it also perceptibly yields at all times, and therefore the tract of the bubbles is formed by a number of curves and not angles.

Hence we may understand the reason why the zig-zag kind of lightning is so dangerous, namely, because it cause it must overcome a very violent resistance of the atmosphere; and wherever that resistance is in the smallest degree lessened, there it will undoubtedly strike, and at a very considerable distance too. It is otherwise with that kind which appears in flashes of no determinate form. The electric matter of which these are composed, is evidently dissipated in the air by some conducting substances which are present there; and of consequence, though a man, or other conducting body, happened to be very near such a flash, he would not be struck or materially injured by it, though a zig-zag flash, in such circumstances, would have probably discharged its whole force upon him.

The most destructive kind of lightning, however, is that which assumes the form of balls. These are produced by an exceeding great power of electricity gradually accumulated till the resistance of the atmosphere is no longer able to confine it. In general, the lightning breaks out from the electrified cloud by means of the approach of some conducting substance; either a cloud, or some terrestrial substance: but the fire-balls seem to be formed, not because there is any substance at hand to attract the electric matter from the cloud, but because the electricity is accumulated in such quantity that the cloud itself can no longer contain it. Hence such balls fly off slowly, and have no particular destination. Their appearance indicates a prodigious commotion and accumulation of electricity in the atmosphere, without a proportionable disposition in the earth to receive it. This disposition, however, we know, is perpetually altered by a thousand circumstances, and the place which first becomes most capable of admitting electricity will certainly receive a fire-ball. Hence this kind of lightning has been known to move slowly backwards and forwards in the air for a considerable space of time, and then suddenly to fall on one or more houses, according to their being more or less affected with an electricity opposite to that of the ball at the time. It will also run along the ground, break into several parts, and produce several explosions at the same time.

It is very difficult to imitate lightning of this kind in our electrical experiments. The only cases in which it hath been done in any degree are those in which Dr Priestley made the explosion of a battery pass for a considerable way over the surface of raw flesh, water, &c. and in Mr Arden's experiment, when a fire-ball ascended to the top of an electrified jar, and burst it with a violent explosion. See ELECTRICITY n° 89, &c. In these cases, if, while the electric flash passed over the surface of the flesh, it had been possible to interrupt the metallic circuit by taking away the chain, the electric matter discharged from the battery would have been precisely in the situation of one of the fireballs.

Why such lightning is very dangerous.

Why lightning assumes the form of balls.

Lightning. balls above-mentioned; *i. e.* it would have been at a loss for a conductor. The negative side of the battery was the place of its destination; but to that it would not have easily got, because of the great quantity of atmosphere which lay in its way, and the incapacity of the neighbouring bodies to receive it. But, while the electric matter was thus stationary for want of a conductor, if any person standing near, or touching the negative side of the battery, presented a finger to that seemingly inoffensive luminous body, he would instantly be struck very violently; because a free communication being now made by means of his body, the powers by which the electric fluid is impelled from one place to another would instantly urge it upon him. But if we suppose a person, who hath no communication with the battery, to present his finger to the same body, he may perhaps receive a slight spark from it; but not a shock of any consequence, because there is not a perfect communication by means of his body with the place to which the electric fire is destined.

Phenomena of lightning in general accounted for. Hence we may account for the seemingly capricious nature of lightning of all kinds, but especially of that kind which appears in the form of balls. Sometimes it will strike trees, high houses, steeples, and towers, without touching cottages, men, or other animals, who are in the neighbourhood. In such cases, people would be apt to say that the neighbourhood of these higher objects *preferred* the others from the stroke; but with little reason, since low houses, men walking in the fields, cattle, nay the surface of the earth itself, have all been struck, while high trees and steeples in the neighbourhood have not been touched. In like manner, fire-balls have passed very near certain persons without hurting them, while they have, as it were, gone considerably out of their way to kill others. The reason of all this is, that in thunder-storms there is constantly a certain zone of earth considerably under the surface, which the lightning desires (if we may use the expression) to strike, because it hath an electricity opposite to that of the lightning itself. Those objects, therefore, which form the most perfect conductors between the electrified clouds and that zone of earth, will be struck by the lightning, whether they are high or low; and because we know not the conducting quality of the different terrestrial substances, the superstitious are apt to ascribe strokes of lightning to the divine vengeance against particular persons, whereas it is certain that this fluid, as well as others, acts according to invariable rules from which it is never known to depart.

Lightning, in the time of severe thunder-forms, is supposed to proceed from the earth, as well as from the clouds: but this fact hath never been well ascertained, and indeed from the nature of the thing it seems very difficult to be ascertained; for the motion of the electric fluid is so very quick, that it is altogether impossible to determine, by means of our senses, whether it goes from the earth or comes to it. In fact, there are in this country many thunder-forms in which it doth not appear that the lightning touches any part of the earth, and consequently can neither go to it nor come out from it. In these cases, it flashes either from an electrified cloud to one endowed with

an opposite electricity, or merely into those parts of **Lightning.** the atmosphere which are ready to receive it. But if not only the clouds, but the atmosphere all the way betwixt them and the earth, and likewise for a considerable space above the clouds, are electrified one way, the earth must then be struck. The reason of this will appear from a consideration of the principles laid down under the article **ELECTRICITY**, sect. vi. It there appears, that the electric fluid is altogether incapable either of *accumulation* or *diminution* in quantity in any particular part of space. What we call *electricity* is only the motion of this fluid made perceptible to our senses. Positive electricity is when the current of electric matter is directed from the electrified body. Negative electricity is when the current is directed towards it. Let us now suppose, that a positively electrified cloud is formed over a certain part of the earth's surface. The electric matter flows out from it first into the atmosphere all round; and while it is doing so, the atmosphere is negatively electrified. In proportion, however, as the electric current pervades greater and greater portions of the atmospheric space, the greater is the resistance to its motion, till at last the air becomes positively electrified as well as the cloud, and then both act together as one body. The surface of the earth then begins to be affected, and it silently receives the electric matter by means of the trees, grass, &c. till at last it becomes positively electrified also, and begins to send off a current of electricity from the surface downwards. The causes which at first produced the electricity of the clouds (and which are treated of under the article **THUNDER**), still continuing to act, the power of the electric current becomes inconceivably great. The danger of the thunder-storm now begins; for as the force of the lightning is directed to some place below the surface of the earth, it will certainly dart towards that place, and slatter every thing to pieces which resists its passage. The benefit of conducting-rods will now also be evident: ¹¹ Use of conducting rods. for we are sure that the electric matter will in all cases take the way where it meets with the least resistance; and this is through the substance, or rather over the surface, of metals. In such a case, therefore, if there happen to be a house furnished with a conductor directly below the cloud, and at the same time a zone of negatively electrified earth not very far below the foundation of the house, the conductor will almost certainly be struck, but the building will be unhurt. If the house wants a conductor, the lightning will nevertheless strike in the same place, in order to get at the negatively electrified zone above mentioned; but the building will now be damaged, because the materials of it cannot readily conduct the electric fluid.

We will now be able to enter into the dispute, **Whether** the preference is due to knobbed or pointed conductors for preferring buildings from strokes of lightning? Ever since the discovery of the identity of electricity and lightning, it hath been allowed by all parties, that conductors of some kind are in a manner essentially necessary for the safety of buildings in those countries where thunder-forms are very frequent. The principle on which they act hath been already explained; namely, that the electric fluid, when impelled by any power, always goes to that place where

Lightning. it meets with the least resistance, as all other fluids also do. As metals, therefore, are found to give the least resistance to its passage, it will always choose to run along a metaline rod, in preference to a passage of any other kind. We must, however, carefully consider a circumstance which seems to have been too much overlooked by electricians in their reasonings concerning the effects of thunder-rods; namely, That lightning, or electricity, never strikes a body, merely for the sake of the body itself, but only because by means of that body it can readily arrive at the place of its destination. When a quantity of electricity is collected from the earth, by means of an electric machine, a body communicating with the earth will receive a strong spark from the prime conductor. The body receives this spark, not because it is itself capable of containing all the electricity of the conductor and cylinder, but because the natural situation of the fluid being disturbed by the motion of the machine, a stream of it is cast off from the earth. The natural powers, therefore, make an effort to supply what is thus drained off from the earth; and as the individual quantity which comes out is most proper for supplying the deficiency, as not being employed in any natural purpose, there is always an effort made for returning it to the earth. No sooner, then, is a conducting body, communicating with the earth, presented to the electrical machine, than the whole effort of the electricity is directed against that body, not merely because it is a conductor, but because it leads to the place where the fluid is directed by the natural powers by which it is governed, and at which it would find other means to arrive, though that body were not to be presented. That this is the case, we may very easily satisfy ourselves, by presenting the very same conducting substance in an insulated state to the prime conductor of the machine; for then we shall find, that only a very small spark will be produced. In like manner, when lightning strikes a tree, a house, or a thunder-rod, it is not because these objects are high, or in the neighbourhood of the cloud; but because they communicate with some place below the surface of the ground, against which the impetus of the lightning is directed; and at that place the lightning would certainly arrive, though none of the above-mentioned objects had been interposed.

The fallacy of that kind of reasoning generally employed concerning the use of thunder-rods, will now be sufficiently apparent. Because a point presented to an electrified body in our experiments, always draws off the electricity in a silent manner; therefore Dr Franklin and his followers have concluded, that a pointed conductor will do the same thing to a thunder-cloud, and thus effectually prevent any kind of danger from a stroke of lightning. Their reasoning on this subject, they think, is confirmed by the following fact among many others. "Dr Franklin's house at Philadelphia was furnished with a rod extending nine feet above the top of the chimney. To this rod was connected a wire of the thickness of a goose-quill, which descended through the wall of the stair-case; where an interruption was made, so that the ends of the wire, to each of which a little bell was fixed, were distant from each other about six inches; an insulated brass

ball hanging between the two bells. The author was Lightning. one night waked by loud cracks, proceeding from his apparatus in the stair-case. He perceived, that the brass ball, instead of vibrating as usual between the bells, was repelled and kept at a distance from both; while the fire sometimes passed in very large quick cracks directly from bell to bell; and sometimes in a continued dense white stream, seemingly as large as his finger; by means of which the whole stair-case was enlightened, as with sun-shine, so that he could see to pick up a pin. - From the apparent quantity of electric matter of which the cloud was thus evidently robbed, by means of the pointed rod (and of which a blunt conductor would not have deprived it), the author conceives, that a number of such conductors must considerably lessen the quantity of electric fluid contained in any approaching cloud, before it comes so near as to deliver its contents in a general stroke."

For this very reason, Mr Benjamin Wilson and his followers, who constitute the opposite party, have determined that the use of pointed conductors is utterly unsafe. They say, that in violent thunder storms the whole atmosphere is full of electricity; and that attempts to exhaust the vast quantity there collected, are like attempting to clear away an inundation with a shovel, or to exhaust the atmosphere with a pair of bellows. They maintain, that though pointed bodies will effectually prevent the accumulation of electricity in any substance; yet if a non-electrified body is interposed between a point and the conductor of an electrical machine, the point will be struck at the same moment with the non-electrified body, and at a much greater distance than that at which a knob would be struck. They affirm also, that, by means of this silent solicitation of the lightning, inflammable bodies, such as gun-powder, tinder, and Kunckel's phosphorus, may be set on fire; and for these last facts they bring decisive experiments. From all this, say they, it is evident that the use of pointed conductors is unsafe. They solicit a discharge to the place where they are; and as they are unable to conduct the whole electricity in the atmosphere, it is impossible for us to know whether the discharge they solicit may not be too great for our conductor to bear; and consequently all the mischiefs arising from thunder-forms may be expected, with this additional and mortifying circumstance, that this very conductor hath probably solicited the fatal stroke, when without it the cloud might have passed harmless over our heads without striking at all.

Here the reasoning of both parties seems equally wrong. They both proceed on this erroneous principle, That in thunder-forms the conductor will always solicit a discharge, or that at such times all the elevated objects on the surface of the earth are drawing off the electricity of the atmosphere. But this cannot be the case, unless the electricity of the earth and of the atmosphere is of a different kind. Now, it is demonstrable, that until this difference between the electricity of the atmosphere and of the surface of the earth ceases, there cannot be a thunder-form. When the atmosphere begins to be electrified either positively or negatively, the earth, by means of the inequalities and moisture of its surface, but especially by the vegetables which grow

Lightning grow upon it, absorbs that electricity, and quickly becomes electrified in the same manner with the atmosphere. This absorption, however, ceases in a very short time, because it cannot be continued without setting in motion the whole of the electric matter contained in the earth itself. Alternate zones of positive and negative electricity will then begin to take place below the surface of the earth, for the reasons mentioned under the article ELECTRICITY, sect. vi. § 9. Between the atmosphere and one of these zones, the stroke of the lightning always will be. Thus supposing the atmosphere is positively electrified, the surface of the earth will, by means of trees, &c. quickly become positively electrified also; we shall suppose to the depth of 10 feet. The electricity cannot penetrate farther on account of the resistance of the electric matter in the bowels of the earth. At the depth of 10 feet from the surface, therefore, a zone of negatively electrified earth begins, and to this zone the electricity of the atmosphere is attracted; but to this it cannot get, without breaking through the positively electrified zone which lies uppermost, and flustering to pieces every bad conductor which comes in its way. We are very sure, therefore, that in whatever places the outer-zone of positively electrified earth is thinnest, there the lightning will strike, whether a conductor happens to be present or not. If there is a conductor, either knobbed or sharp-pointed, the lightning will indeed infallibly strike it; but it would also have struck a house situated on that spot, without any conductor; and though the house had not been there, it would have struck the surface of the ground itself.—Again, if we suppose the house with its conductor to stand on a part of the ground where the positively electrified zone is very thick, the conductor will neither silently draw off the electricity, nor will the lightning strike it, though perhaps it may strike a much lower object, or even the surface of the ground itself, at no great distance; the reason of which undoubtedly is, that there the zone of positively electrified earth is thinner than where the conductor was.

We must also observe, that the Franklinians make their pointed conductors to be of too great consequence. To the houses on which they are fixed, no doubt, their importance is very great: but in exhausting a thunder-cloud of its electricity, their use must appear trifling; and to insist on it, ridiculous. Innumerable objects, as trees, grass, &c. are all conspiring to draw off the electricity, as well as the conductor, if it could be drawn off; but of effecting this there is an impossibility, because they have the same kind of electricity with the clouds themselves. The conductor hath not even the power of *attracting* the lightning a few feet out of the direction which it would choose of itself. Of this we have a most remarkable and decisive instance in what has happened to the magazine at Purfleet in Essex, on May 15. 1777. That house was furnished with a pointed conductor, raised above the highest part of the building; nevertheless, about six in the evening of the abovementioned day, a flash of lightning struck an iron cramp in the corner of the wall considerably lower than the top of the conductor, and only 46 feet in a sloping line distant from the point.—This produced a long dispute with Mr Wilson concerning the propriety of using pointed conductors; and, by the

favour of his majesty, he was enabled to construct a Lightning more magnificent electrical apparatus than any private person could be supposed to erect at his own expense, and of which some account is given under the article ELECTRICITY, n° 83. The only new experiments, however, which this apparatus produced, were the firing of gunpowder by the electric *aura* as it is called; and a particularly violent shock which a person received when he held a small pointed wire in his hand, upon which the conductor was discharged. We must observe, that the electrified surface of the conductor was 620 feet; and we can have but little idea of the strength of sparks from a conductor of this magnitude, supposing it properly electrified. Six turns of the wheel made the discharge felt through the whole body like the strong shock of a Leyden vial; and nobody chose to make the experiment when the conductor had received a higher charge. A very strong shock was felt, as already observed, when this conductor was discharged upon a pointed wire held in a person's hand, even though the wire communicated with the earth; which was not felt, or but very little, when a knobbed wire was made use of. To account for this difference may, perhaps, puzzle electricians; but with regard to the use of blunt or pointed thunder-rods, both experiments seem quite inconclusive. Though a very great quantity of electric matter silently drawn off will fire gunpowder, this only proves that a pointed conductor ought not to pass through a barrel of gunpowder; and if a person holding a pointed wire in his hand received a strong shock from Mr Wilson's great conductor, it can thence only be inferred, that in the time of thunder nobody ought to hold the conductor in their hands; both which precautions common sense would dictate without any experiment. From the accident at Purfleet, however, the disputants on both sides ought to have seen, that, with regard to lightning, neither points nor knobs can *attract*. Mr Wilson surely had no reason to condemn the pointed conductor for *soliciting* the flash of lightning, seeing it did not strike the point of the conductor, but a blunt cramp of iron; neither have the Franklinians any reason to boast of its effect in *silently drawing off* the electric matter, since all its powers were neither able to prevent the flash, nor to turn it 46 feet out of its way. The matter of fact is, the lightning was determined to enter the earth at the place where the board-house stands, or near it. The conductor fixed on the house offered the easiest communication: but 46 feet of air intervening between the point of the conductor and the place of explosion, the resistance was less through the blunt cramp of iron, and a few bricks moistened with rain-water, to the side of the metalline conductor, than through the 46 feet of air to its point; for the former was the way in which the lightning actually passed.

Mr Wilson and his followers seem also mistaken in supposing that a pointed conductor can solicit a greater discharge than what would otherwise happen. Allowing the quantity of electricity in the atmosphere during the time of a thunder-storm to be as great as they please to suppose; nevertheless, it is impossible that the air can part with all its electricity at once, on account of the difficulty with which the fluid moves in it. A pointed conductor, therefore, if it does any thing at all, can only solicit the partial discharge which

^{Lightning.} which is to be made at any rate: and if none were to be made though the conductor was absent, its presence will not be able to effect any.

An objection to the use of conductors, whether blunt or pointed, may be drawn from the accident which happened to the poor-house at Heckingham, which was struck by lightning though furnished with eight pointed conductors; but from an accurate consideration of the manner in which the conductors were situated, it appears, that there was not a possibility of their preventing any stroke. See Philosophical Transactions, Vol. LXXII. p. 361.

¹³
Lord Ma-
hon's theo-
ry of light-
ning.

In a late publication on the subject of electricity by Lord Mahon, we find a new kind of lightning made mention of, which he is of opinion may give a fatal stroke, even though the main explosion be at a considerable distance; a mile, for instance, or more. This he calls the *electrical returning stroke*; and exemplifies it in the following manner, from some experiments made with a very powerful electrical machine, the prime conductor of which (six feet long, by one foot diameter) would generally, when the weather was favourable, strike into a brass ball connected with the earth, to the distance of 18 inches or more. In the following account, this brass ball, which we shall call *A*, is supposed to be constantly placed at the *striking distance*; so that the prime conductor, the instant that it becomes fully charged, explodes into it.

Another large conductor, which we shall call the *second conductor*, is suspended, in a perfectly insulated state, farther from the prime conductor than the *striking distance*, but within its *electrical atmosphere*; at the distance of *six feet*, for instance. A person standing on an insulating stool touches this *second conductor* very lightly with a finger of his right hand; while, with a finger of his left hand, he communicates with the earth, by touching very lightly a second brass ball fixed at the top of a metallic stand, on the floor, and which we shall call *B*.

While the prime conductor is receiving its electricity, sparks pass (at least if the distance between the two conductors is not too great) from the second conductor to the insulated person's right hand; while similar and simultaneous sparks pass out from the finger of his left hand into the second metallic ball *B*, communicating with the earth. These sparks are part of the *natural quantity* of electric matter belonging to the second conductor, and to the insulated person; driven from them into the earth, through the ball *B*, and its stand, by the elastic pressure or action of the electrical atmosphere of the prime conductor. The second conductor and the insulated person are hereby reduced to a *negative state*.

At length, however, the prime conductor, having acquired its *full charge*, suddenly strikes into the ball *A*, of the first metallic stand, placed for that purpose at the *striking distance* of 17 or 18 inches. The explosion being made, and the prime conductor suddenly robbed of its electric atmosphere, its pressure or action on the second conductor, and on the insulated person, as suddenly ceases; and the latter instantly feels a smart *returning stroke*, though he has no direct or visible communication (except by the floor) either with the *striking* or *struck* body, and is placed at the distance of *five or six feet* from both of them. This returning stroke

is evidently occasioned by the sudden *re-entrance* of the *Lightning*, to electric fire *naturally* belonging to his body and to the second conductor, which had before been expelled from them by the action of the charged prime conductor upon them; and which returns to its former place the instant that action or elastic pressure ceases. The author shows, that there can be no reason to suppose that the electrical discharge from the prime conductor should in this experiment *divide itself* at the instant of the explosion, and go different ways, so as to strike the second conductor and insulated person in this manner, and at such a distance from it.

When the second conductor and the insulated person are placed in the *densest* part of the electrical atmosphere of the prime conductor, or *just beyond* the striking distance, the effects are still more considerable; the *returning stroke* being extremely severe and pungent, and appearing considerably sharper than even the *main stroke* itself, received directly from the prime conductor.

This circumstance the author alleges as an unanswerable proof that the effect which he calls the *returning stroke*, was not produced by the *main stroke* being any wise *divided* at the time of the explosion, since no effect can ever be greater than the *cause* by which it is *immediately* produced.—Having taken the *returning stroke* eight or ten times one morning, he felt a considerable degree of pain across his chest during the whole evening, and a disagreeable sensation in his arms and wrists all the next day.

We come now to the application of this experiment, and of the doctrine deduced from it, to what passes in *natural electricity*, or during a thunder-storm; in which there is reason to expect similar effects, but on a larger scale:—a scale so large indeed, according to the author's representation, that persons and animals may be destroyed, and particular parts of buildings may be considerably damaged, by an electrical *returning stroke*, occasioned even by some *very distant explosion* from a thunder-cloud:—possibly at the distance of a mile or more.

It is certainly easy to conceive, that a charged extensive thunder-cloud must be productive of effects similar to those produced by the author's prime conductor. Like it, while it continues charged, it will, by the *superinduced elastic electrical pressure* of its atmosphere, to use the author's own expression, drive into the earth a part of the electric fluid *naturally* belonging to the bodies which are within the reach of its *widely extended atmosphere*; and which will therefore become *negatively electrical*. This portion too of their electric fire, as in the artificial experiments, will, on the explosion of the cloud, at a *distance*, and the cessation of its action upon them, suddenly *return* to them; so as to produce an equilibrium, and restore them to their *natural state*.

To this theory, the authors of the Monthly Review ¹⁴ Answered have given the following answer: "We cannot, how-by the Re-
viewers. ever, agree with the ingenious author, with respect to the *greatness* of the effects, or of the danger to be apprehended from, the *returning stroke* in this case; as we think his estimate is grounded on an erroneous foundation.—Since (says he) the density of the electrical atmosphere of a *thunder-cloud* is so *immense*, when compared to the electrical density of the electrical atmosphere of any *prime conductor*, charged by means of any electri-
cal

Lightning—*cal apparatus whatsoever*; and since a *returning stroke*, when produced by the sudden removal of even the *weak* elastic electrical pressure of the electrical atmosphere of a charged *prime conductor*, may be extremely *strong*, as we have seen above; it is *mathematically evident*, that, when a *returning stroke* comes to be produced by the sudden removal of the very strong elastic electrical pressure of the electrical atmosphere of a thunder-cloud powerfully charged; the strength of such a *returning stroke* must be enormous.*

"If indeed the quantity of electric fluid *naturally* contained in the body of a man, for instance, were immense, or indefinite, the author's estimate between the effects producible by a cloud, and those caused by a prime conductor, might be admitted. But surely an electrified cloud,—how great soever may be its extent, and the height of its charge when compared with the extent and charge of a prime conductor—cannot expel from a man's body (or any other body) *more* than the *natural* quantity of electricity which it contains. On the sudden removal, therefore, of the pressure by which this natural quantity had been expelled, in consequence of the explosion of the cloud into the earth; *no more* (at the utmost) than his *whole natural stock* of electricity can re-enter his body (c). But we have no reason to suppose that this quantity is so great, as that its sudden re-entrance into his body should destroy or even injure him.

"In the experiment above described, the insulated person receives into his body, at the instant of the *returning stroke*, not only all that portion of his own natural electric fire which had been expelled from it; but likewise transmits through it, at the same instant, in consequence of his peculiar situation, all the electric fire of which the large second conductor had been robbed; and which must necessarily re-pass through his body, to arrive at that conductor. To render the case somewhat parallel, in *natural electricity*, the man's body must be so peculiarly circumstanced, supposing him to be in a house, that the electric matter which has been expelled from the house into the earth, by the pressure of an extensive thunder-cloud, could not return back into the building, on the explosion of the cloud at a distance, without passing through his body: a case not likely to happen, unless the house were insulated (like the second conductor in the preceding experiment), and his body became the channel through which alone the house could have its electric matter restored to it; it appears much more probable that the electric matter returns to the house through the *same channels* by which it before insensibly passed out, and with equal silence, though more suddenly.

"In the case of a man who is abroad, and in an *open field*, during the time of an explosion:—as he is unconnected with other masses of matter *above him*, no more than the precise quantity of electric fire, which had been before expelled from his body, will *suddenly* return into it at the instant of a distant explosion: and that this quantity is not usually very large, may be inferred from many considerations.

"When a person standing on the ground holds a pair of Mr Canton's balls in his hand, while a highly charged thunder-cloud is suspended over his head; the angle made by the balls indicates the *electrical state* of that person, or the quantity of *natural electricity* of which his body is at that time deprived, by the action of the (*positively*) charged cloud hanging over him. But we have never seen the repulsion of the balls so considerable, as to furnish any just apprehensions that the return of his natural electric matter, however sudden, could be attended with injury to him: nor would he be sensible of any commotion on the balls suddenly coming together; though a spark might undoubtedly be perceived, at that instant, were he insulated, and placed in the same manner with the author when he tried the above-related experiment.

"The author nevertheless observes, that 'there have been instances of persons who have been killed by *natural electricity*, having been found with their *shoes torn*, and with their *feet* damaged by the electrical fire; but who have not had, over their whole body, any other apparent marks of having been struck with lightning.' He adds, 'if a man walking out of doors were to be killed by a *returning stroke*, the electrical fire would rush into that man's body through his *feet*, and his feet only; which would not be the case, were he to be killed by any *main stroke* of explosion, either positive or negative.'

"It would be no difficult task, we think, to account for these appearances in a different manner; were all the circumstances attending the case minutely ascertained: but without interrogating the *dead* on this subject, we may more satisfactorily appeal to the experience of the *living* (v), to show, that though the *returning stroke* must take place, in all thunder-forms, in some degree or other; yet it is not of that alarming magnitude which the author ascribes to it. If, in any particular thunder-form, a man in the open fields could be killed, at the instant of a distant explosion, merely by the return of his *own* electric fire, which had before been driven out of his body; surely numerous observations of persons who had experienced the *returning stroke*, in *slighter* degrees, would be familiar; and scarce a great thunder-form must have occurred, in which

one

(c) "We suppose the person not to be so situated, that the *returning fire* of other bodies must necessarily pass through his body."

(d) "The author does indeed produce a *living* evidence, in the case of a person at Vienna, who, he has been credibly informed, received an electrical shock, by having held one hand accidentally in contact with an interrupted metallic conducting rod, at the instant that a thunder-cloud exploded at the distance, as was conjectured, of above half an English mile. He likewise observes, that a 'very strong, bright, and sudden stroke' (or spark) of electrical fire has been seen, by several electricians, to pass in the interval, or interruption, purposely left in the conducting rod of a house at the instant of a distant explosion; and 'when it was fully proved, by the sharp point of the conductor not being melted, or even tinged,' that the conductor itself had not been struck.—These observations, however, do not by any means prove the magnitude or danger of the *returning stroke*, but merely its *existence*; which we do not question."

Lightning. one person or another must not, at the instant of an explosion, have felt the effects of the *returning stroke*, in *some degree or other*—from that of a violent *concussion*, to that of a slight and almost imperceptible *puffation*. But no observations of this kind are known to us; nor have we ever heard of any person's experiencing any kind of electrical commotion in a thunder-storm, except such as have either been directly struck, or have happened to be in the *very near neighbourhood* of the spot where the explosion took place.

"The author has been aware of this objection, which he proposes, and endeavours to remove: but his answer to it amounts to little more than what has been already quoted from him; that is, to a simple estimate of the enormous difference between the electrical density, or the *elastic electrical pressure*, of the atmosphere of an extensive *thunder cloud*, and that of a charged *prime conductor*. We have already observed, that this is not the proper method of estimating their different effects, when these two causes, how unequal soever in power, are considered as exerting that power on bodies containing a *limited* and comparatively *small*, quantity of electric matter.

"We have been induced to discuss this subject thus particularly, with a view to quiet the minds of the timorous; as the author's extension of his principles, respecting the returning stroke in *artificial electricity*, to what passes in *natural electricity*, holds out a new, and, in our opinion, groundless subject of terror to those who, in the midst of their apprehensions, have hitherto only dreaded the effects of a thunder-storm when it made near approaches to them; but who, if this doctrine were believed, would never think themselves in security while a thunder-cloud appeared in sight, unless sheltered in a house furnished with proper conductors:—for we should not omit to remark, that a subsequent observation tends to diminish their fears, by showing that *high* and *pointed* conductors tend to secure both persons and buildings against the various effects of any *returning stroke* whatever, as well as of the *main stroke*."

A late melancholy accident which happened in Scotland has afforded Lord Mahon an opportunity of bringing additional arguments in favour of his system. An account of this accident is given by Patrick Brydone, Esq; F. R. S. in the 77th volume of the Philosophical Transactions. It happened on the 19th of July 1785, near Coldstream on the Tweed. The morning was fine, with the thermometer at 68°; but about eleven o'clock the sky became obscured with clouds in the south-east: and betwixt twelve and one a storm of thunder and lightning came on. This storm was at a considerable distance from Mr Brydone's house, the intervals between the flash and crack being from 25 to 30 seconds, so that the place of explosion must have been betwixt five and six miles off: but while our author was observing the progress of the storm, he was suddenly surprised with a loud report, neither preceded nor accompanied by any flash of lightning, which resembled the explosion of a great number of muskets, in such quick succession, that the ear could scarcely discriminate the sounds. On this the thunder and lightning instantly ceased, the clouds began to separate, and the sky soon recovered its serenity. In a little time Mr Brydone was informed, that

N° 182.

a man with two horses had been killed by the *thunder*. **Lightning.** der; and, on running out to the place, our author found the two horses lying on the spot where they had been first struck, and still yoked to the cart. As the body of the man who was killed had been carried off, Mr Brydone himself had not an opportunity of examining it, but was informed by Mr Bell, minister of Coldstream, who saw it, that the skin of the right thigh was much burnt and shrivelled; that there were many marks of the same kind all over the body, but none on the legs: his clothes, particularly his shirt, had a strong smell of burning; and there was a zig-zag line of about an inch and a quarter broad, extending from the chin to the right thigh, and which seemed to have followed the direction of the buttons of his waistcoat. The body was buried in two days without any appearance of putrefaction.

Mr Brydone was informed by another person who accompanied him that was killed, of the particular circumstances. They were both driving carts loaded with coals; and James Lauder, the person who was killed, had the charge of the foremost cart, and was sitting on the fore part of it. They had crossed the Tweed a few minutes before at a deep ford, and had almost gained the highest part of an ascent of about 65 or 70 feet above the bed of the river, when he was stunned with the report above mentioned, and saw his companion with the horses and cart fall down. On running up to him, he found him quite dead, with his face livid, his clothes torn in pieces, and a great smell of burning about him. At the time of the explosion he was but about 24 yards distant from Lauder's cart, and had him full in view when he fell, but felt no shock, neither did he perceive any flash or appearance of fire. At the time of the explosion his horses turned round, and broke their harness. The horses had fallen on their left side, and their legs had made a deep impression on the dust; which, on lifting them up, showed the exact form of each leg, so that every principle of life seemed to have been extinguished at once, without the least struggle or convulsive motion. The hair was singed over the greatest part of their bodies; but was most perceptible on their belly and legs. Their eyes were dull and opaque, as if they had been long dead, though Mr Brydone saw them in half an hour after the accident happened. The joints were all supple, and he could not observe that any of the bones were broken or dissolved, as is said to be sometimes the case with those who are killed by lightning. The left shaft of the cart was broken, and splinters had been thrown off in many places; particularly where the timber of the cart was connected by nails or cramps of iron. Many pieces of the coal were thrown to a considerable distance; and some of them had the appearance of being some time on a fire. Lauder's hat was torn into innumerable small pieces; and some part of his hair was strongly united to those which had composed the crown of it. About four feet and a half behind each wheel of the cart he observed a circular hole of about 20 inches diameter, the centre of which was exactly in the track of each wheel. The earth was torn up as if by violent blows of a pick-axe; and the small stones and dust were scattered on each side of the road. The tracks of the wheels were strongly marked in the dust, both before and behind these holes, but did not in the smallest

15
Remark-
able acci-
dent by an
electrical
explosion
from the
earth.

Lightning. smallest degree appear on the spots themselves for upwards of a foot and a half. There were evident marks of fusion on the iron rings of the wheels; the surface of the iron, the whole breadth of the wheel, and for the length of about three inches, was become bluish, had lost its polish and smoothness, and was formed into drops which projected sensibly, and had a roundish form; but the wood did not appear any way injured by the heat which the iron must have conceived. To determine whether these were made by the explosion which had torn up the ground, the cart was pushed back on the same tracks which it had described on the road; and the marks of fusion were found exactly to correspond with the centres of the holes. They had made almost half a revolution after the explosion; which our author ascribes to the cart being pulled a little forward by the fall of the horses. Nothing remarkable was observed on the opposite part of the wheel. The broken ground had a smell something like that of ether; the soil itself was very dry and gravely.

The catastrophe was likewise observed by a shepherd, at the distance of about 200 or 300 yards from the spot. He said, that he was looking at the two carts going up the bank when he heard the report, and saw the foremost man and horses fall down; but observed no lightning, nor the least appearance of fire, only he saw the dust rise about the place. There had been several flashes of lightning before that from the south-east; whereas the accident happened to the north-west of the place where he stood. He was not sensible of any shock.

Our author next gives an account of several phenomena which happened the same day, and which were evidently connected with the explosion. A shepherd tending his flock in the neighbourhood, observed a lamb drop down; and said, that he felt at the same time as if fire had passed over his face, though the lightning and claps of thunder were at a considerable distance. He ran up to the creature immediately, but found it quite dead; on which he bled it with his knife, and the blood flowed freely. The earth was not torn up; nor did he observe any dust rise, though he was only a few yards distant. This happened about a quarter of an hour before Lauder was killed, and the place was only about 300 yards distant.

About an hour before the explosion, two men standing in the middle of the Tweed, fishing for salmon, were caught in a violent whirlwind, which felt sultry and hot, and almost prevented them from breathing. They could not reach the bank without much difficulty and fatigue; but the whirlwind lasted only a very short time, and was succeeded by a perfect calm.

A woman making hay, near the banks of the river, fell suddenly to the ground, and called out that she had received a violent blow on the foot, and could not imagine from whence it came; and Mr Bell, the minister above mentioned, when walking in his garden, a little before the accident happened to Lauder, felt several times a tremor in the ground.

The conclusion drawn from these facts by Brydone is, that at the time of the explosion the equilibrium between the earth and the atmosphere seems to have been completely restored, as no more thunder was heard nor lightning observed; the clouds were dispelled, and the atmosphere resumed the most perfect tranquillity: "But how this vast quantity of electric matter (says he) could be discharged from the one ele-

ment to the other, without any appearance of fire, I shall not pretend to examine. From the whole it would appear, that the earth had acquired a great superabundance of electrical matter, which was every where endeavouring to fly off into the atmosphere. Perhaps it might be accounted for from the excessive dryness of the ground, and for many months the almost total want of rain, which is probably the agent that nature employs in preserving the equilibrium between the two elements."

Lord Malton, now Earl Stanhope, whose observations on this accident are published in the same volume, endeavours to establish the following positions as facts.

1. That the man and horses were not killed by any *direct main stroke of explosion* from a thunder-cloud either positively or negatively electrified.

2. They were not killed by any *transmitted main stroke* either positive or negative.

3. The mischief was not done by any *lateral explosion*. All these are evidently true, at least with respect to lightning at that time falling from the clouds; for all the lightning which had taken place before was at a great distance.

4. They were not suffocated by a sulphureous vapour or smell which frequently accompanies electricity. This could not account for the pieces of coal being thrown to a considerable distance all round the cart, and for the splinters of the wood which were thrown off from many parts of the cart.

5. It might be imagined by some that they were killed by the violent commotion of the atmosphere, occasioned by the vicinity of the electrical explosion, in a manner similar to the fatal wounds that sometimes have been known to have been given by the air having been suddenly displaced by a cannon-ball in its passage through the atmospherical fluid, though the cannon-ball itself had evidently neither struck the person wounded nor grazed his clothes. The dust that rose at the time of the explosion might be brought as an argument in favour of the opinion, that a sudden and violent commotion of the air did occasion the effects produced. But such an explanation would not account for the marks of fusion on the iron of the wheels, nor for the hair of the horses being singed, nor for the skin of Lauder's body having been burnt in several places.

6. From these different circumstances his Lordship is of opinion, that the effects proceeded from electricity; and that *no electrical fire did pass* immediately, either from the clouds into the cart, or from the cart into the clouds. From the circular holes in the ground, of about 20 inches diameter, the respective centres of which were exactly in the track of each wheel, and the corresponding marks of fusion in the iron of the wheels, it is evident that the electrical fire did pass from the earth to the cart, or from the cart to the earth, through that part of the iron of the wheels which was in contact with the ground. From the splinters which had been thrown off in many places, particularly where the timber was connected by nails or cramps of iron, and from various other effects mentioned in Mr Brydone's account, it is evident, that there must have been a great commotion in the electrical fluid in all, or at least in different parts of the cart, and in the bodies of the man and horses, although there was no lightning.

7. All these phenomena, his Lordship argues, may be explained in a satisfactory manner from the doctrine

17
Arguments
drawn by
Earl Stan-
hope in fa-
vour of his
system.

Lightning. already laid down concerning the returning stroke. Before entering upon the subject of the main explosion, however, he takes notice of the other phenomena already mentioned in Mr Brydones account.

With regard to the case of the lamb, his lordship is of opinion, that it belongs to the most simple class of returning strokes, *viz.* that which happens at a place where there is neither thunder nor lightning near; and that it may be produced by the sudden removal of the elastic electrical pressure of the electrical atmosphere of a single main cloud, as well as of an assemblage of clouds. It appears (says he) by Mr Brydones account, that the shepherd who saw the lamb fall, was near enough to it to feel, in a small degree, the electrical returning stroke at the same time that the lamb dropped down.—The blow which the woman received on the foot was unquestionably the returning stroke. When a person walking, or standing, out of doors, is knocked down or killed by the returning stroke, the electrical fire must rush in, or rush out, as the case may be, through that persons feet, and through them only; which would not be the case were the person to be killed by any main stroke of explosion either positive or negative.

8. In order to account for the manner in which the man and horses were killed, his lordship premises, that, according to Mr Brydones account, the cloud must have been many miles in length; inasmuch as just before the report, the lightning was at a considerable distance, *viz.* between five and six miles. The loud report resembled the firing of several muskets so close together, that the ear could scarcely separate the sounds, and was followed by no rumbling noise like the other claps. This indicates, that the explosion was not far distant, and likewise that it was not extremely near: for, if the explosion had been very near, the ear could not at all have separated the sounds.

¹⁸
Hypothesis
by which
he accounts
for the phe-
nomena.
9. Let us now suppose a cloud, eight, ten, or twelve miles in length to be extended over the earth, and let another cloud be situated betwixt that and the earth; let them also be supposed charged with the same kind of electricity, and both positive. Let us farther suppose the lower cloud to be near the earth, only a little beyond the striking distance; and the man, cart, and horses, to be situated under that part of the cloud which is next the earth, and to be exactly as described by Mr Brydone, *viz.* near the summit of an hill, and followed by another a little farther down; and let us suppose the two clouds to be near each other just over the place where the man and horses are: Let the remote end of the cloud approach the earth, and discharge its electricity into it. In this case the following effects will take place.

10. When the upper cloud discharges its electricity into the earth from the remote end, the lower cloud will discharge its electricity into the nearer end of the upper cloud, which is supposed to be directly over the place of the cart and horses, or nearly so. This accounts for the loud report of thunder that was unaccompanied by lightning. The report must be loud from its being near; but no lightning could be perceived, by reason of the thick cloud situated immediately between the spectator and the space betwixt the two clouds where the lightning appears.

11. As the lower cloud gradually approached towards the earth, that part of the latter where the man

and horses were, must of course become superinduced by the elastic electrical pressure of the electrical atmosphere of the thunder-cloud; which superinduced elastic electrical pressure must gradually have increased as the cloud came closer to the earth, and approached nearer to the limit of the striking distance.

12. Hence, if any conducting body (not having prominent or conducting points) were to be placed upon the surface of the earth, and there electrically insulated; then such conducting body, by the laws of electricity, must, at its upper extremity (namely the part nearest to the positive cloud) become negative; at its lower extremity it must become positive; and, at a certain intermediate point, it will be neither plus nor minus. This insulated conducting body, thus situated, will be in three opposite states at the same time, that is to say, it will be, at the same time, positively electrified, negatively electrified, and not electrified at all.—For a demonstration of this proposition, his lordship refers to his Principles of Electricity; but it is a generally known and established fact in electricity.

13. If this conducting body on the surface of the earth be not insulated, or be but imperfectly insulated, then the whole of such body, from its being immersed in the electrical atmosphere of the positive cloud, will become negative; because part of the electricity of the conducting body will in this case pass into the earth, and the conducting body will become the more negative as it becomes the more deeply immersed into the dense part of the elastic electrical atmosphere of the approaching thunder-cloud.

14. When the lower cloud comes suddenly to discharge with an explosion its superabundant electricity into the upper one, then the elastic electrical atmosphere of the former will cease to exist; consequently the electrical fluid, which had been gradually expelled into the common stock from the conducting body on the surface of the earth, must, by the sudden removal of the superinduced elastic electrical pressure of the electrical atmosphere of the thunder-cloud, suddenly return from the earth into the said conducting body, producing a violent commotion similar to the pungent shock of a Leyden jar in its sensation and effects.

15. This, which his lordship calls the *electrical re-* ¹⁹
turning stroke, he supposes to have been what killed the man and horses in the present case, they having become strongly negative before the explosion. The man, according to Mr Brydones account, was sitting when he received the stroke, and his legs were hanging over the fore part of the cart at the time of the explosion. The returning stroke, therefore, could not enter his body through the legs; and this accounts for the skin of his legs not having been at all burnt or shrivelled, as the skin was on many other parts of his body; and it likewise shows the reason why the zig-zag line, which was terminated by the chin, did not extend lower than the thigh.

16. Mr Brydone likewise informs us, that the hair of the horses was much singed over the greater part of their bodies, but was most perceptible on the belly and legs. This is easily accounted for by the returning stroke; for the lower part of the bodies of these animals must of course have been more affected than any other part, as the electrical fire must have rushed suddenly into their bodies through their legs, which had made a deep impression on the dust.

Lightning

¹⁹
Supposed
effects of
the return-
ing stroke.

Lightning.

17. The various effects produced on the cart may be explained also from the returning stroke with equal facility. The splinters were thrown off by reason of the interruption of good conductors; the wood being a much less perfect conductor than the iron. It is also evident, that it was the electrical returning fire that produced the marks of fusion on that part of the iron of the wheels which was in contact with the ground; inasmuch as the whole electricity, at the instant of the explosion, did enter at these places.

18. No person in the leaf verified in the principles of electricity can hesitate to assent to the proposition, that the electrical returning stroke must exist under circumstances similar to those explained above; but it may be objected, as the reviewers formerly did, that the quantity of electricity naturally contained in the body of a man, &c. is by far too small to produce such violent effects. For an answer to this objection, his lordship refers to his book: By way of corroboration, however, he makes the following remarks.

20
Great
strength of
force of a
returning
stroke in
certain
cases.

19. No person can reasonably conclude, that the force of a returning stroke must always be weak when produced by the disturbed electrical fluid of a man's body, by reason that a man's body contains but a small quantity of electricity: for it has never been proved that a man's body contains only a small quantity of electrical fluid; neither is there the smallest reason to believe such an hypothesis, which appears, on many accounts, to be completely erroneous; and if that hypothesis be erroneous, the objection to the strength of an electrical returning stroke remains altogether unsupported by argument. "When a body is said to be *plus* or *positive* (says his lordship), it simply means, that the body contains more than its natural share of electricity, but does not say that it is completely saturated with it. In like manner, when a body is said to be *minus* or *negative*, it only signifies, that the body contains *less* than its natural share of electricity; but does not imply that such body is *completely exhausted* of the electricity which it contains in its natural state. "Now (says he), the strength of natural electricity is so immense, when compared with the very weak effects of our largest and best contrived electrical machines, that I conceive we cannot, by means of artificial electricity, excel, from a man's body, thousandth, or perhaps the ten-thousandth part of the electrical fluid which it contains when in its natural state."

20. An hypothesis which easily accounts for any natural phenomenon has a much better claim to our attention than an opposite one, which prevents it from being intelligibly explained. There is no reason to conclude that any electrical machine, of any given size, is capable of rendering a conducting body either *completely plus* or *completely minus*; but far otherwise. And it would have been as logical for any person some years ago (when electrical machines were not brought to their present state) to have maintained, that those very imperfect machines were capable of rendering a body *completely positive* or *completely negative*, as for us to pretend to do it at this day. We evidently have not, with our machines, even approached the limit of electrical strength, particularly in respect to the returning stroke: for it is remarkable, that, by the laws of electricity, the strength of the electrical returning stroke, near the limit of the striking distance, does increase in a

greater ratio than the strength of the main stroke from the charged body producing the elastic electrical atmosphere superinduced. Thus, let us attempt to produce the returning stroke by means of a metallic conductor of about 20 or 21 inches in length and of about two inches in diameter; and by means of another metallic body of equal dimensions placed parallel to the prime conductor, just out of the limit of the striking distance; and let the prime conductor be charged by one of the common glass globes of less than nine inches in diameter; the returning stroke in this case will be so weak, that it can hardly be said to exist: but if the experiment be made by means of a large cylinder, and by means of a metallic prime conductor of about three feet four inches long, by nearly four inches and an half diameter, and also by means of another metallic body of equal dimensions with this prime conductor, then there will be no kind of comparison betwixt the strength of the returning stroke obtained out of the striking distance, and the strength of the main stroke received immediately from the prime conductor; the sharpness and pungency of the returning stroke being so much superior. The returning stroke in this case is like the sudden discharge of a weakly electrified Leyden jar, provided due attention be paid to the rules for obtaining a strong returning stroke.

21. In the case of a returning stroke, the strength depends, according to his lordship's hypothesis, not so much on the *quantity* of the electric fluid, as on its *velocity*; whence also it depends less on the quantity of surface used than on the strength of the electrical pressure of the elastic electrical atmosphere superinduced upon the body struck previous to the explosion. But the electrical pressure of the elastic electrical atmosphere of the great thunder-cloud which produced the mischief on the present occasion, must have been immensely greater than that of a metallic prime conductor; and it is not surprising that the effects should be proportioned to the causes.

22. His lordship next accounts for the returning stroke not being felt by the man who followed Lau-^{Why the} der's cart. This, he thinks, may in some degree be accounted for by the latter having been higher up the bank; though it may better be done by supposing, that the cloud to have been pending nearer the earth over the spot where Launder was killed, than over the place where his companion was; for, in order to receive a dangerous returning stroke, it is necessary that he should be immersed, not merely in the cloud's atmosphere, but in the dense part of the cloud's electrical atmosphere. It may also be accounted for by supposing that the second cart were either better connected with the common stock, or better insulated; for either of these circumstances will weaken a returning stroke prodigiously. Now Mr Brydone mentions, that there had been an almost total want of rain for many months. He also says, that the ground, at the place where Launder was killed, was remarkably dry, and of a gravelly soil. This state of the ground was particularly adapted to the production of the electrical returning stroke, when produced upon the large scale of nature, where the elastic electrical pressure is so powerful.

To these arguments adduced by his lordship for the existence and strength of the electrical returning stroke, we shall add an account of some experiments published

Lightning,
21
Strength of

ing stroke
in different
circumstan-
ces.

22
Why the
returning
stroke was
not felt by
the man
who drove
the second
cart.

Lightning, in the Gentleman's Magazine for 1785. They were made with an insulated rod of iron of considerable length, rising some feet higher than a common conductor placed at the other end of the house. A set of bells were affixed to the former, which in a thunder storm, even when the thunder was four or five miles distant, were rung by the electricity of the atmosphere; but whenever a flash of lightning burst from the cloud, even though at the distance just mentioned, the *same flash*, according to our author, passed through the conductor also, and the bells ceased to ring sometimes for several seconds; then they began again, and continued to ring till they were stopped by another flash. This flash which passed thro' the conductor was undoubtedly what earl Stanhope calls the *returning stroke*; of which we must now give some explanation: And in considering the whole doctrine of that stroke, together with the particular explanation laid down by his lordship, the following observations naturally occur.

1. In the experiments made by his lordship to demonstrate the existence of the returning stroke, there is a deception, of which the reviewers take notice, *viz.* that the man touches a large prime conductor, which, by the operation of the machine, becomes negatively electrified as well as himself. Hence when the discharge is made, all the fire returning to that conductor must pass through his body as well as that of which his body itself is supposed to be deprived; and this, though no other cause intervened, must nearly double the strength of the shock. To make the experiment more fairly, it would be necessary to take away this second conductor, and let the man only touch the brass ball communicating with the earth.

2. In this experiment there is another deception, not taken notice of by the reviewers, *viz.* that any body immersed in a positive electrical atmosphere becomes negative. Hence the second conductor, by being applied to the air positively electrified by the machine, becomes almost as strongly negative as if another machine had been applied to it on purpose; and this negative electricity will be the stronger in proportion to the strength of electricity in the air surrounding it. Again, it is well known that a plate of air may be charged by means of two smooth pieces of metal held at a small distance from each other, one of them connected with an electrical machine, and the other with the earth. Now supposing, instead of the usual communication, that a man standing upon an insulating stool, held the lower metallic plate in one hand, and with the other hand touched the earth, or a conductor communicating with it, it is plain, that by touching the upper plate, the electricity acquired by the air between them would be discharged, and that the man would feel what earl Stanhope calls the *returning stroke*; but which in truth is the shock of a charged electric substance, and would therefore be proportionably pungent. Now, in his lordship's experiments, the two conductors answer exactly to the two metallic plates above mentioned; the air between them, receives a charge, and is discharged by the explosion from the prime conductor, because this conductor forms one of the charging plates. It is true, that the round shape of the conductors renders them unfavourable for trying the experiment; and this is one reason why it re-

quires a great power of electricity to make the return-lightning stroke sensible. The thickness of the plate of air interpolated betwixt the two conductors is another reason; but this makes no difference as to the principles; for his lordship's experiment is undoubtedly no other than that of the Leyden phial. Were his lordship to use two flat plates instead of round conductors, the deception would then be removed; and we may venture to determine *à priori*, that the returning stroke would then be not only very severe, but even *dangerous*, with a very powerful machine and large plates.

3. Though the second conductor were entirely removed, yet there would still be a deception in this experiment, for then the surface of the man's body would act in some measure as one of the metallic plates; so that still the experiment would be on the principles of the Leyden phial, though much weaker than before.

4. In order to make this experiment absolutely without deception, the man should stand upon the ground without touching any thing; and in that case we may should be venture to affirm, that he would feel no returning shock. His being insulated varies the nature of the experiment entirely, as will easily be understood from the following considerations.

Under the article **ELECTRICITY**, we have shown, that *positive* electricity does not consist in an accumulation, nor *negative* electricity in a deficiency, of the fluid; but that all electric phenomena are to be accounted for from the mere *motion* of the fluid, and that this motion is always a circulation. We have shown, that in the working of a common machine, the electric fluid comes from the earth; that it is accumulated around the prime conductor; evaporates in the air; and is then silently absorbed by the earth, and recondensed to the machine. Hence, in the charging of a machine which works positively, the earth, and all bodies on its surface, for some way round, are in a negative state; because they are then absorbing the electrical fluid from the atmosphere. That part of the earth indeed directly under the feet of the machine, and perhaps some little way farther, is *positive*; because it is *giving out* electricity; but the negative portion will be much more extensive. When the conductor is discharged by a spark, then the circulation ceases in a great measure by the collision of the two opposite streams of electric matter. All bodies on the surface of the earth, then, as far as it was negatively electrified, must receive what his lordship calls the *returning stroke*; but the electricity being diffused among such a number, and over such a wide extent, it is no wonder that it should be insensible. If, however, we insulate a large conducting body, and then make another part of it communicate with the earth by means of a good conductor, we instantly put it in a situation fit for transmitting more than its share of the electricity of the atmosphere, and reducing it to the state of the insulated rubber of an electrical machine, through which the whole quantity of electricity must pass to the phial held towards it, in order to be charged negatively. In proportion to this quantity transmitted the shock must be, not because the conductor has lost a large share of its *natural* electricity, but because a large quantity is *artificially* made to pass through it. We may therefore safely venture to assert, that, in thunder storms, unless a body transmits *more* than

23
Experiments with an insulated conductor.

24
Deceptions in Earl Stanhope's experiments.

25
Returning stroke not different from that of a charged phial.

26
How the experiment should be properly made.

27
Another explanation of the phenomena.

Lightning: *than its natural proportion* of electric fluid, no shock will be felt, much less can the person be killed.

28
Difficulties which occur in his Lordship's hypothesis.

5. In his explanation of the accident which happened to Lauder, his lordship is reduced to the greatest difficulty, and makes one of the most unphilosophical shifts in the world; no less than that of arranging the clouds of heaven, not according to fact, but according to his own imagination. He supposes the existence of two clouds, one below the other; and ascribes to them various motions and situations, which we have already taken notice of; but who knows whether such clouds ever existed? His Lordship does not pretend that any body ever saw them; and thus he runs into what is termed by logicians a *vicious circle*; he first assumes data, purposely made to accord with his hypothesis, and then proves the hypothesis from the data.

6. Granting the arrangement of the clouds, and every thing that his lordship desires, the main requisite is still wanting, viz. a flash of lightning at a distance to produce the returning stroke. According to him, the distant flash and returning stroke must be simultaneous; but Mr Brydone mentions no such thing: on the contrary, there had been no flash for some little time before; and the immense velocity of the electric fluid will not allow us to suppose that it would take up the usual time betwixt thunder-claps in traveling five or six miles.

7. His lordship accounts for no lightning being seen at the time of the explosion in a very arbitrary and unnatural manner, by supposing it to have proceeded from a discharge of the one imaginary cloud into the other; and that it was not *seen* on account of the thickness of the lower cloud. A much more natural supposition must be, that it happened below the cart-wheels, but was not seen on account of its being daylight, and the cloud of dust which it raised. The succession of noises, too, indicated a succession of explosions, the flashes of which would be less easily observed than a single large one.

8. It seems altogether impossible, that the *return* of any quantity of natural electricity into a body should shatter that body to pieces. In the present case, the fire entered by a small part of the iron of the wheels, and this part was melted. His lordship does not hesitate to own, that the fusion was a proof that the *whole* fire belonging to the cart, man, and horses, or at least to the cart and man, had entered by this part of the wheels, and consequently more than naturally belonged to that small part of iron. The same evidence, however, will hold good with regard to every other part. We grant that the fire entered the man's body by his right thigh: this might have therefore been burnt by receiving the fire belonging to the whole body; but it ought then to have quietly diffused itself through the other parts of his body, or at least if any damage had been done, it ought to have been done only to the internal parts. Instead of this, a broad zig-zag line upon his body indicated a vast quantity of electric matter running along the surface without entering the body at all. In like manner, his hat being torn in pieces, indicated a violent explosion of electric matter at his head, where there ought to have been little or no explosion, as none could be wanted there except what the *hat* had parted with; and it is ridiculous to sup-

pose that *hats* part with such quantities of electricity as would tear them in pieces by its return. The shivering of the cart, the burning and throwing about of the coals, and all the other circumstances of the case, also point out in the clearest manner, not a quantity of electric matter returning to supply any natural deficiency, but an enormous explosion of that matter from the earth overwhelming and destroying whatever stood in its way. That two explosions were made from the earth is very evident, because there were two holes in it; and the very size of these holes indicates a much greater discharge of electricity than we can *reasonably* suppose to have been lost by the man, horses, and cart.

29
Phenomena of the insulated thunder-rod accounted for.

We shall now consider the experiment quoted from the correspondent in the Gentleman's Magazine. These, as well as the accident under consideration, undoubtedly show, that, during the time of a thunder-storm, both atmosphere and earth are affected for a very considerable way. With regard to the *quantity* of this electrical affection, however, though it must undoubtedly be excessive when taken all together, we can by no means agree that it is so taken partially. From an experiment related in the Magazine above quoted, it appears, that the electricity of a violent thunder-storm extends sometimes over a circle of 100 miles diameter. "Electricity (says the author) seldom appeared without a shower; but I was surprised, on the 5th of June 1784, that the bells rang with thin and very high clouds, and without the least appearance of rain, till the next post brought me an account of a violent thunder-storm, and very destructive hail, at a village 50 miles distant." We cannot by any means suppose, that all this space was electrified like a charged phial; otherwise, great as the explosions of lightning are, they would still be much greater. This is evident even in our electrical machines. A single phial may be charged much higher than a battery, as appears by the electrometer; but the battery, though less charged, will have incomparably more power than a single phial. His lordship appears to have deceived himself in this matter, by mistaking the *extent* of the electrified surface for the *quantity* of charge in every part of it. The surface of the earth in a thunder-storm is exactly similar to that of a charged conductor. According to the extent of electrified surface, the spark will be great or small; and just so it is with lightning, for some kinds of it are much more destructive than others. In all cases, however, the *quantity* of electricity in a particular spot is very inconsiderable. Lightning strikes bodies, not because they are highly electrified, but because they afford a communication betwixt the atmosphere and some place below the surface of the earth. This stroke is the aggregate of the whole electricity contained in a circle of probably many miles in diameter; but the returning stroke, if bodies are in their natural state, can only be in proportion to the *quantity* of electricity in each substance contained within that space. It is in fact the lightning itself diffused through the earth which makes the returning stroke; and it is impossible that every substance within two or three miles of the explosion can receive the whole flash, or another equal to it. It is only in cases where the quantity of electricity diffused through a great space, happens to discharge

Lightning. itself through a human body or other conducting substance of no great bulk, that the effects upon the latter can be any way considerable. This was undoubtedly the case with the thunder-rod mentioned by the correspondent in the Magazine; for it received either from the atmosphere or from the earth, at the time of every flash, the whole quantity of electricity which had been diffused for a considerable way round. Pointed bodies, we know, draw off electricity very powerfully; inasmuch that an highly charged jar may be deprived of almost all its power by merely presenting a needle to it. We can be at no loss therefore to understand why a pointed conductor should draw off the electricity from a large portion of the surface of the earth, or from a considerable portion of atmosphere.

We must now, however, inquire into the reason of these appearances of sparks in places at such distance from the explosion of the lightning. To understand this, we must always keep in our eye that principle so fully explained under the article **ELECTRICITY**, viz. that there never is, nor can be, a real deficiency of the electric fluid in any substance or in any place. It is to be considered as an absolute *plenum*, and of consequence it can have no other motion than a circulatory one. At every discharge of lightning therefore from the clouds into the earth, or from one cloud into another, there must be a return of the same quantity to those clouds which have made the discharge. In the vast extent of electrified surface, some part of these returns must undoubtedly be made at great distances from the place where the explosion of lightning happens. As long as matters remain in their natural state, the electric matter will return by innumerable passages in such small streams, that no perceptible effect upon any single substance can take place. But if a body be so situated, that a large portion of the electric matter must return through it from the earth, then such body will undoubtedly be more affected by every flash than the rest of the substances around it; and if the communication with the earth be interrupted, a flash of fire will be perceived betwixt the conducting substance and the earth at the time that a flash bursts out from the cloud. The strength of such a flash, however, must by no means be supposed equivalent to that of the *main* stroke of lightning, unless we could suppose the whole electrical power of the vast circle already mentioned to be discharged through the conductor.

31
Particular
explanation
of the acci-
dent.

But though this may explain the reason of the sparks or flashes observed in the case of the thunder-rod just mentioned, we cannot from this principle account for the accident which befel the man and horses. There was indeed at that time a very violent emission of electricity from the earth, but no distant flash of lightning happened at the same moment with it, to expel the electricity from the earth. It appears therefore, that the electricity had in this case been accumulating in the earth itself, in a manner similar to that which produces earthquakes; and which is fully explained under that article. The thunder-storm was the natural means employed to supply that part of the earth with electricity, which was in the state of charging; and the moment that the quantity thus supplied was thrown back, all signs of electricity must

cease, as much as when that thrown in upon one side of a Leyden phial is again thrown off. Hence, when the flash burst out of the earth, and killed the man and horses, that portion of earth which absorbed the electricity till then, required it no longer; and of consequence the thunder-storm occasioned by this absorption naturally ceased.

That this disposition to an earthquake did really prevail in the earth at that time, is evident from the tremor which Mr Bell felt on the ground when walking in his garden. The stroke which the woman received on the foot, the death of the lamb, and no doubt many similar circumstances, concurred to show that there was an attempt to restore the equilibrium from the earth, as has been already related. The same disposition to an earthquake, however, was afterwards renewed; and on the 11th of August that same year, a smart shock of an earthquake did actually take place, as Mr Brydone informs us in the same paper.

Besides the different kinds of lightning already treated of, it is by no means uncommon to see flashes unattended by any report. There are always of the sheet kind; they happen very frequently in windy weather when the sky is clear; and likewise when the sky is cloudy, immediately before a fall of rain or snow. The general reason of these appears to be, that the electric fluid is the medium by which the vapours are suspended in the atmosphere; and of consequence, every separation of vapour, whether as rain, snow, or hail, must be attended with what is called a *discharge* of electrical matter. The reason why this kind of lightning is never attended with any report is, that there is no particular object against which the force of the flash is directed; but it dissipates itself among the innumerable conducting bodies with which the atmosphere always abounds. It is, however, in a manner impossible to explain the various ways in which this subtle fluid acts. We know not, for instance, in what state it is when acting as a medium of connection betwixt the air and vapour, nor in what its *discharge* into other parts of the atmosphere properly consists. At any rate, we see that a flash of lightning, however limited its extent may appear to us, diffuses its effects over a great space of atmosphere; for after one of these silent flashes, it is no uncommon thing to observe the sky to become obscure though it had been quite serene before; or, if it had been cloudy, to see rain or snow begin to fall in a very few minutes. It is probable indeed, that there is no change whatever that can take place in the atmosphere but by means of electricity; and there is great reason to believe, that the silent discharges of this fluid from one part of the atmosphere to another, many of which are totally invisible, ultimately occasion the whole of the phenomena of **METEOROLOGY**. See that article.

Various parts of his Lordship's Treatise on Elec-Directions³² tricity, besides those already quoted, tend to prove for conducting the utility of *high* and *pointed* conductors, in pre- rods.
ference to those which terminate in a *ball*, or *rounded end*. Towards the end of the performance, the author discusses this matter very particularly; and enumerates the '*necessary requisites*' in erecting them, in number 11; to every one of which we readily sub-

Lightning. subscribe. As this matter is of a popular nature, and on a subject generally interesting, we shall transcribe this list; adding a short explanation to particular articles.—These requisites (says the author) are 11 in number.

‘1st, That the rod be made of such substances as are, in their nature, the *best conductors of electricity*.

‘2dly, That the rod be *uninterrupted, and perfectly continuous*.—This is a very material circumstance. One entire piece of metal cannot perhaps be had: but it is not sufficient that the rods, of which the conductor consists, be *sensibly* in contact; they should be pressed into *actual* contact by means of nuts and screws, with a thin piece of sheet-lead between the shoulders of the joints.

‘3dly, That it be of a *sufficient thickness*.—A copper rod half an inch square, or an iron rod one inch square, or one of lead two inches square, are thought fully sufficient by the author.

‘4thly, That it be perfectly connected with the common stock.—That is, it should be carried deep into the earth, which is frequently dry near the surface; and then continued in a horizontal direction, so as to have the farther extremity dipped, should this be practicable, into water, at the distance of 10 yards or more from the foundation.

‘5thly, That the upper extremity of the rod be as *acutely pointed* as possible.—This termination should be of copper; or rather a very fine and exceedingly acute needle of *gold* should be employed, which will not materially add to the expence.

‘6thly, That it be very finely tapered:—so that the upper extremity may be a cone, the diameter of the base of which may bear an extremely small proportion to its height; for instance, that of *one to forty*.

‘7thly, That it be extremely prominent;—that is, 8, 10, or 15 feet at least above the highest parts of the building. The author lays great stress on this circumstance; in consequence of the law above-mentioned, deduced by him from his experiments, relating to electric atmospheres. According to this law, the density of an electric atmosphere (the *negative* atmosphere, for instance, of the roof of a house, &c. while a *positively* charged cloud hangs over it) diminishes in the inverse ratio of the *square* of the distance from the surface of the body to which that atmosphere belongs. Accordingly, if the rod project 12 feet into this atmosphere, it will reach to a part of it *four* times less dense than if the rod projected only to *half* that distance, or six feet;—and to a part *one hundred and forty* four times rarer, than if it projected only *one foot*.

‘8thly, That each rod be carried, in the shortest convenient direction, from the point at its upper end, to the common stock.

‘9thly, That there be neither large nor prominent bodies of metal upon the top of the building proposed to be secured, but such as are connected with the conductor, by some proper metallic communication.

‘10thly, That there be a *sufficient number* of high and pointed rods.—On edifices of great importance, especially magazines of gun-powder, the author thinks there ought never to be above 40 or 50 feet asunder.

‘11thly, That every part of the rods be very substantially erected.’

The author declares that he has ‘never been able **Lightning.** to hear of a *single* instance, nor does he believe that any one can be produced, of an *high, tapering, and acutely pointed* metallic conductor, having ever, in any country, been struck by lightning; if it had *all* the necessary requisites abovementioned, especially the second and fourth.’

On the whole, it seems to be pretty certain, that both pointed and knobbed metalline conductors have the power of preserving any body placed at a small distance from them from being struck by lightning. This they do, not because they can *attract* the lightning far out of its way, but because the resistance to its passage is always least on that side where they are; and as pointed conductors diminish the resistance more considerably than blunt ones, they seem in all cases to be preferable.—It appears, however, that a single conductor, whether blunt or pointed, is not capable of securing all the parts of a large building from strokes of lightning; and therefore several of them will be required for this purpose; but to what distance their influence extends, hath not been determined, nor does it seem easily capable of being ascertained.

It now remains only to explain some of the more uncommon appearances and effects of lightning. One of these is, that it is frequently observed to kill alternately: that is, supposing a number of people standing in a line; if the first person was killed, the second perhaps would be safe; the third would be killed, and the fourth safe; the fifth killed, &c.—Effects of this kind are generally produced by the most violently kind of lightning; namely, that which appears in the form of balls, and which are frequently seen to divide themselves into several parts before they strike. If one of these parts of a fire-ball strike a man, another will not strike the person who stands immediately close to him; because there is always a repulsion between bodies electrified the same way. Now, as these parts into which the ball breaks have all the same kind of electricity, it is evident that they must for that reason repel one another; and this repulsion is so strong, that a man may be interposed within the stroke of two of them, without being hurt by either.

The other effect of lightning is mentioned under the article JERUSALEM, where those who attempted to rebuild the temple had the marks of crosses imprinted upon their garments and bodies. This may reasonably be thought to arise from the same cause to which the angular appearance of lightning in the air is owing, namely, its violent impetus and velocity, together with the opposition of the atmosphere. A small stroke of lightning, sometimes indeed a very considerable one, cannot always enter the substance of terrestrial bodies, even when it touches them, for reasons already given. In this case it runs along their surface, and, as in its motion it is perpetually resisted by the atmosphere, it undoubtedly has the same angular motion which we often perceive in the atmosphere. If in this situation it happens to touch the human skin, or a garment, especially of linen, as being a conductor, it will undoubtedly leave a mark upon it; and this mark being of a zig-zag form, might, in the above instance, have been either taken for the exact form of a cross.

Lightning
||
Lignum.

cross by the beholders, or have suggested that idea in relating the story to make it appear more wonderful.

These observations may serve to give some idea of the nature of lightning, and its operations after it appears in its proper form and bursts out from the cloud; but for an account of its original formation, and of the powers by which the clouds are at first electrified, and their electricity kept up notwithstanding many successive discharges of lightning, and the quantity of electric matter continually carried off by the rain, &c. see the article THUNDER.

Artificial LIGHTNING. Before the discoveries of Dr Franklin concerning the identity of electricity and lightning, many contrivances were invented in order to represent this terrifying phenomenon in miniature: the combustions of phosphorus in warm weather, the ascension of the vapour of spirit of wine evaporated in a close place, &c. were used in order to support the hypotheses which at that time prevailed; namely, that lightning was formed of some sulphurous, nitrous, or other combustible vapours, floating in long trains in the atmosphere, which by some unaccountable means took fire, and produced all the destructive effects of that phenomenon. These representations, however, are now no more exhibited; and the only true artificial lightning is universally acknowledged to be the discharge of electric matter from bodies in which it is artificially set in motion by our machines.

LIGHTNING was looked upon as sacred both by the Greeks and Romans, and was supposed to be sent to execute vengeance on the earth: Hence persons killed with lightning, being thought hateful to the gods, were buried apart by themselves, lest the ashes of other men should receive pollution from them. Some say they were interred upon the very spot where they died; others will have it that they had no interment, but were suffered to rot where they fell, because it was unlawful for any man to approach the place. For this reason the ground was hedged in, lest any person unawares should contract pollution from it. All places struck with lightning were carefully avoided and fenced round, out of an opinion that Jupiter had either taken offence at them, and fixed upon them the marks of his displeasure, or that he had, by this means, pitched upon them as sacred to himself. The ground thus fenced about was called by the Romans *lidentul*. Lightning was much observed in augury, and was a good or bad omen, according to the circumstances attending it.

LIGNICENCIS TERRA, in the materia medica, the name of a fine yellow bole dug in many parts of Germany, particularly about Emeric in the circle of Westphalia, and used in cordial and astringent compounds.

LIGNUM VITÆ. See GUIACIUM.

LIGNUM Aloë. See EXCOECARIA.

LIGNUM Nephriticum. See GUIALANDINA.

LIGNUM Rhodium, or *Rosewood*, in the materia medica; a wood, or root, chiefly brought to us from the Canary islands. The writers on botany and the materia medica are much divided about the lignum rhodium, not only with regard to the plant which affords it, but likewise in their accounts of the drug itself, and

have described, under this name, *simples* manifestly different. This confusion seems to have arisen from an opinion, that the *rhodium*, and the *aspalathus* (an article of considerable esteem among the ancients, but with regard to which the moderns are very much at a loss), are the same; whence different woods brought into Europe for the unknown *aspalathus*, were fold again by the name of *rhodium*.

In those modern pharmacopœias which admit the lignum rhodium, different Linnæan names are at present given to it: thus the authors of the Dispensatorium Brunsvicensis suppose it to be the *Rhodola rosa* of Linnæus; and those of the Pharmacopœia Rossica, the *Genista Canariensis*. As to *Aspalathus*, the ancients themselves disagree; Dioscorides meaning by this appellation the wood of a certain shrub freed from the bark, and Galen the bark of a root. At present we have nothing under this name in the shops. What was heretofore fold among us as *aspalathus*, were pieces of a pale-coloured wood brought from the East Indies, and more commonly called *calambour*.

The *aspalathus*, *calambour*, and lignum aquila, are supposed to be woods of the nature of *gallochum*, or lignum aloë, but weaker in quality. The lignum rhodium of the shops is usually in long crooked pieces, full of knots, which when cut appear of a yellow colour like box, with a reddish cast: the largest, smoothest, most compact, and deepest coloured pieces, should be chosen; and the small, thin, or pale ones, rejected. The taste of this wood is lightly bitterish, and somewhat pungent; its smell is very fragrant, resembling that of roses: long kept, it seems to lose its smell; but on cutting, or rubbing one piece against the other, it smells as well as at first. Distilled with water, it yields an odoriferous essential oil, in very small quantity. Rhodium is at present in esteem only upon account of its oil, which is employed as an high and agreeable perfume in scenting pomatums and the like. But if we may reason from analogy, this odoriferous sumple might be advantageously applied to more useful purposes; a tincture of it in rectified spirit of wine, which contains in small volume the virtue of a considerable deal of the wood, bids fair to prove a serviceable cordial, not inferior perhaps to any thing of this kind.

LIGNUM Campechense. See HEMATOXILUM.

LIGNUM Cuburinum. See OPHIORHIZA.

LIGULATED, among botanists, an appellation, given to such floccules as have a straight end turned downwards, with three indentures, but not separated into segments.

LIGURIA (anc. geog.), a country of Italy, bounded on the south by the Mediterranean sea, on the north by the Appennine mountains, on the west by part of Transalpine Gaul, and on the east by Etruria. There is a great disagreement among authors concerning the origin of the Ligurians, though most probably they were descended from the Gauls. Some carry up their origin as far as the fabulous heroes of antiquity; while others trace them from the Ligyes, a people mentioned by Herodotus as attending Xerxes in his expeditions against Greece. These Ligyes are by some ancient geographers placed in Colchis; by others, in Albania. According to Diodorus Siculus, the Ligurians led a very wretched life; their country

Lignum
||
Liguria.

Ligusticum,
Ligustrum.

being entirely overgrown with woods, which they were obliged to pull up by the roots, in order to cultivate their land, which was also encumbered with great stones, and, being naturally barren, made but very poor returns for all their labour. They were much addicted to hunting; and, by a life of continual exercise and labour, became so strong, that the weakest Ligurian was generally an overmatch for the strongest and most robust among the Gauls. The women are said to have been almost as strong as the men, and to have borne an equal share in all laborious enterprises. With all their bravery, however, they were not able to resist the Roman power; but were subdued by that warlike nation, about 211 B. C.

LIGUSTICUM, LOVAGE, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatae*. The fruit is oblong, and quinquelobed on each side; the florets are equal; the petals involuted or rolled inwards, and entire. There are seven species; of which the most remarkable are, the levisium or common, and the foticum or Scots lovage. The first is a native of the Apennine mountains in Italy. It has a thick fleshy, deeply-penetrating perennial root, crowned by very large, many-parted, radical leaves, with broad lobes, having incisions at top, upright, strong, channelled stalks, branching six or seven feet high, and all the branches terminated by yellow flowers in large umbels. The second is a native of Scotland, and grows near the sea in various parts of the country. It has a thickish, fleshy, penetrating, perennial root, crowned by large doubly-trifoliated leaves, with broad, short, indented lobes, upright round stalks, half a yard high, terminated by small yellow umbels. Both species are hardy, and easily propagated by seeds sown in spring or autumn.

Medicinal uses, &c. The root of the first species agrees nearly in quality with that of angelica: the principal difference is, that the lovage root has a stronger smell, and a somewhat less pungent taste, accompanied with a more durable sweetness, the seeds being rather warmer than the root; but although certainly capable of being applied to useful purposes, this root is not regarded in the present practice. The leaves of the second are sometimes eaten raw as a salad, or boiled as greens, by the inhabitants of the Hebrides. The root is reckoned a good carminative. They give an infusion of the leaves in whey to their calves to purge them.

LIGUSTRUM, PRIVET, in botany: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 44th order, *Separiæ*. The corolla is quadrifid; the berry tetraspermous. There is but one species; of which there are two varieties, the deciduous and the evergreen. They are hardy plants, rising from 10 to 15 feet high, adorned with oblong entire leaves, and spikes of infundibuliform oblong white flowers, succeeded by black-berries. They are easily propagated by seed, layers, suckers, or cuttings. They are used for making hedges. The purple colour upon cards is prepared from the berries. With the addition of alum, these berries are said to dye wool and silk of a good and durable green; for which purpose they must be

VOL. X. Part I.

gathered as soon as they are ripe. The leaves are bitter and slightly astringent. Oxen, goats, and sheep, eat the plant; horses refuse it.

LILBURNE (John), an enthusiastic demagogue, who was tyrannically punished by the star-chamber court, being put in the pillory, whipped, fined, and imprisoned, for importing and publishing seditious pamphlets, which he had got printed in Holland; they chiefly reflected on the church of England and its bishops: he suffered in 1637, and in prison was doubly loaded with irons. In 1641, he was released by the long parliament; and from this time, he had the address to make himself formidable to all parties, by his bold, aspiring genius. He signalized himself in the parliament army; and was at one time the secret friend and confidant of Cromwell, and at another his avowed enemy and accuser; so that, in 1650, Cromwell found it to be his interest to silence him, by a grant of some forfeited estates. But after this, he grew outrageous against the protector's government; became chief of the levellers; and was twice tried for high treason, but acquitted by the juries. The last was for returning from exile (having been banished by the parliament) without a pass. He died in 1657, aged 88.

LILIACEOUS, in botany, an appellation given to such flowers as resemble those of the lily.

LILIUM, the LILY, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronariæ*. The corolla is hexapetalous, and campanulate, with a longitudinal nectariferous line or furrow; the capsules connected by small cancellated hairs. There are many species; all of them bulbous-rooted, herbaceous, flowery perennials, rising with erect annual stalks three or four feet high, garnished with long narrow leaves, and terminated by fine clusters of large, bell-shaped, hexapetalous flowers of exceeding great beauty, of white, red, scarlet, orange, purple, and yellow colours.

Culture. All the species are propagated by sowing the seeds; and if care is taken to preserve these seeds from good flowers, very beautiful varieties are often produced. The manner of sowing them is as follows: Some square boxes should be procured, about six inches deep, with holes bored in the bottoms to let out the wet: these must be filled with fresh, light, sandy earth; and the seeds sown upon them pretty thick in the beginning of August, and covered over about half an inch deep with light sifted earth of the same kind. They should then be placed where they may have the morning sun; and if the weather proves dry, they must be watered at times, and the weeds carefully picked out. In the month of October the boxes are to be removed to a place where they may have as much sun as possible, and be secured from the north and north-east winds. In spring the young plants will appear, and the boxes are then to be removed into their former situation. In August the smallest roots are to be emptied out of these boxes, and sowed over a bed of light earth, and covered with about half an inch depth of earth of the same kind sifted over them. Here they must be watered, and shaded at times, and defended from the severity of winter by a light covering of straw or pease-haulm in the hardest weather. In

Lilburne,
Lilium.

February, the surface of the bed should be cleared, and a little light earth sifted over it. When the leaves are decayed, the earth should be a little stirred over the roots; and in the month of September following some more earth sifted on. In the September of the following year, the roots must be transplanted to the places where they are to remain, and set at the distance of eight inches; the roots being placed four inches below the surface: this should be done in moist weather. They will now require the same care as in the preceding winters; and, the second year after they are transplanted, the strongest roots will begin to flower. The fine ones should then be removed at the proper season into flower beds, and planted at great distances from one another that they may flower strong.

Medical uses. The roots of the white lily are emollient, maturing, and greatly suppurative. They are used externally in cataplasms for these purposes with success. The common form of applying them is boiled and bruised; but some prefer the roasting them till tender, and then beating them to a paste with oil, in which form they are said to be excellent against burns. Gerard recommends them internally against dropries.

The Kamtschatkene, or Kamtschatka lily, called there *faranne*, makes a principal part of the food of the Kamtschatkans. Its roots are gathered by the women in August, dried in the sun, and laid up for use: they are the best bread of the country; and after being baked are reduced to powder, and serve instead of flour in soups and several dishes. They are sometimes washed, and eaten as potatoes; are extremely nourishing, and have a pleasant bitter taste. Our navigators boiled and eat them with their meat. The natives often parboil, and beat it up with several sorts of berries, so as to form of it a very agreeable confection. Providentially it is an universal plant there, and all the grounds bloom with its flower during the season. Another happiness remarked there is, that while fish are scarce the *faranne* is plentiful; and when there is a dearth of this, the rivers pour in their provisions in redoubled profusion. It is not to the labours of the females alone that the Kamtschatkans are indebted for these roots. A species of mouse saves them a great deal of trouble. The *faranne* forms part of the winter provisions of that little animal: they not only gather them in the proper season, and lay them up in their magazines, but at times have the instinct of bringing them out in sunny weather to dry them, lest they should decay. The natives search for their hoards; but with prudent tenderness leave part for the owners, being unwilling to suffer such useful caterers to perish.

LILLO (George), an excellent dramatic writer, born at London in 1693. He was a jeweller by profession, and followed his business for many years in that neighbourhood with the fairest reputation. He was at the same time strongly attached to the muses, yet seemed to have laid it down as a maxim, that the devotion paid to them ought always to tend to the promotion of virtue, morality, and religion. In pursuance of this aim, Lillo was happy in the choice of his subjects, and showed great power of affecting the heart, by working up the passions to such a height, as to render the distresses of common and domestic life equally interesting to the audiences as that of kings

and heroes, and the ruin brought on private families by an indulgence of avarice, lust, &c. as the havoc made in states and empires by ambition, cruelty, or tyranny. His "George Barnwell," "Fatal Curiosity," and "Arden of Feverham," are all planned on common and well-known stories; yet they have perhaps more frequently drawn tears from an audience than the more pompous tragedies of Alexander the Great, All for Love, &c. In the prologue to "Emeric," which was not acted till after the author's death, it is said, that when he wrote that play, he "was depressed by want," and afflicted by disease; but in the former particular there appears to be evidently a mistake, as he died possessed of an estate of L. 60 a-year, besides other effects to a considerable value. His death happened in 1739, in the 47th year of his age. His works have been lately collected, and published, with an account of his life, in 2 vols 12mo, by Mr T. Davis.

LILLY (John), a dramatic poet, was born in the wilds of Kent, about the year 1553, and educated in Magdalen-college, Oxford, where he took the degree of bachelor of arts in 1573, and that of master in 1575. From Oxford he removed to Cambridge; but how long he continued there, is uncertain. On his arrival in London, he became acquainted with some of Queen Elizabeth's courtiers, by whom he was cherished, and admired as a poet and a wit; and her majesty, on particular festivals, honoured his dramatic pieces with her presence. His plays are nine in number. His first publication, however, printed in 1580, was a romance called *Euphues*, which was universally read and admired. This romance, which Blount, the editor of six of his plays, first introduced a new language, especially among the ladies, is, according to Berkenhout, in fact a most contemptible piece of affectation and nonsense: nevertheless it seems very certain, that it was in high estimation by the women of fashion of those times, who, we are told by Whalley the editor of Ben Jonson's works, had all the phrases by heart; and those who did not speak *Euphuism* were as little regarded at court as if they could not speak French. "He was (says Oldys) a man of great reading, good memory, ready faculty of application, and uncommon eloquence; but he ran into a vast excess of allusion." When or where he died is not known. Anthony Wood says he was living in 1597, when his last comedy was published. After attending the court of Queen Elizabeth 13 years, notwithstanding his reputation as an author, he was under a necessity of petitioning the queen for some small stipend to support him in his old age. His two letters or petitions to her majesty on this subject are preserved in manuscript.

LILLY (William), a noted English astrologer, born in Leicestershire in 1602; where his father not being able to give him more learning than common writing and arithmetic, he resolved to seek his fortune in London. He arrived in 1620, and lived four years as a servant to a mantua-maker in the parish of St Clements Danes; but then moved a step higher to the service of Mr Wright, master of the Salter's company in the Strand, who not being able to write, Lilly among other offices kept his books. In 1627, when his master died, he paid his addresses to the widow, whom he married with a fortune of 1000*l*. Being now

Lilly
||
Lilyæum.

his own master, he followed the puritanical preachers; and, turning his mind to judicial astrology, became pupil to one Evans, a profligate Welsh parson, in that pretended art. Getting a MS. of the *Ars notitia* of Corn. Agrippa, with alterations, he drank in the doctrine of the magic circle, and the invocation of spirits, with great eagerness. He was the author of the *Merlinus Anglicus junior*; *The Supernatural Sight*; and *The White King's Prophecy*. In him we have an instance of the general superstition and ignorance that prevailed in the time of the civil war between Char. I. and his parliament: for the king consulted this astrologer, to know in what quarter he should conceal himself, if he could escape from Hampton court; and general Fairfax, on the other side, sent for him to his army, to ask him if he could tell by his art, whether God was with them and their cause? Lilly, who made his fortune by favourable predictions to both parties, assured the general that God would be with him and his army. In 1648, he published his *Treatise of the three Suns* seen the preceding winter; and also an astrological judgment upon a conjunction of Saturn and Mars. This year the council of state gave him in money 50*l.* and a pension of 100*l.* *per annum*, which he received for two years, and then resigned on some disgust. In June 1660, he was taken into custody by order of the parliament, by whom he was examined concerning the person who cut off the head of king Charles I. The same year he sued out his pardon under the great seal of England. The plague raging in London, he removed with his family to his estate at Hertham; and in October 1666 was examined before a committee of the house of commons concerning the fire of London, which happened in September that year. After his retirement to Hertham, he applied himself to the study of physic, and, by means of his friend Mr Ashmole, obtained from archbishop Sheldon a licence for the practice of it. A little before his death he adopted for his son, by the name of *Merlin junior*, one Henry Coley, a taylor by trade; and at the same time gave him the impression of his almanac, after it had been printed for 36 years. He died in 1681 of a dead palsy. Mr Ashmole set a monument over his grave in the church of Walton upon Thames. His "Observations on the Life and Death of Charles late King of England," if we overlook the astrological nonsense, may be read with as much satisfaction as more celebrated histories; Lilly being not only very well informed, but strictly impartial. This work, with the *Lives of Lilly and Ashmole*, written by themselves, were published in one vol. 8vo, in 1774, by Mr Burnan.

LILY, in botany. See LILIUM.

LILY of the Valley. See CONVALLARIA.

LILYBÆUM (anc. geog.), a city of Sicily, situated on the most westerly promontory of the island of Sicily, and said to have been founded by the Carthaginians on their expulsion from Motya by Dionysius tyrant of Syracuse. It is remarkable for three sieges it sustained; one against Dionysius the tyrant, another against Pyrrhus king of Epirus, and the third against the Romans. The two first failed in their attempts, but the Romans with great difficulty made themselves master of it. No remains of this once state-

ly city are now to be seen, except some aqueducts and temples; though it was standing in Strabo's time.

LILYE (William,) the grammarian, was born in the year 1466 at Oldham in Hampshire; and in 1486, was admitted a senui-commoner of Magdalen college, in Oxford. Having taken the degree of bachelor of arts, he left the university, and travelled to Jerusalem. Returning from thence, he continued five years in the island of Rhodes, where he studied the Greek language, several learned men having retired thither after the taking of Constantinople. From Rhodes he travelled to Rome; where he improved himself in the Greek and Latin languages, under Sulpitius and P. Sabinus. He then returned to London, where for some time he taught a private grammar-school, being the first person who taught Greek in the metropolis. In 1510, when Dr Colet founded St Paul's school, Lilye was appointed the first master; at which time, it seems, he was married and had many children. In this employment he had laboured 12 years, when, being seized by the plague, which then raged in London, he died in February 1523, and was buried in the north yard of St Paul's. He had the character of an excellent grammarian, and a successful teacher of the learned languages. His principal work is *Brevissima institutio, seu ratio grammaticæ cognoscenda*; Lond. 1513. Reprinted times without number, and commonly called *Lilye's grammar*. The English rudiments were written by Dr Colet, dean of St Paul's; and the preface to the first edition, by cardinal Wolsey. The English syntax was written by Lilye; also the rules for the genders of nouns, beginning with *Propria quæ maribus*; and those for the preterperfect tenses and supines, beginning with *Ac in presenti*. The Latin syntax was chiefly the work of Erasmus. See Ward's preface to his edition of Lilye's Grammar, 1732.

LIMA, a city of South America, in Peru, of which it is capital, with an archbishop's see, and an university. It gives its name to the principal audience of Perú; and is surrounded with brick-walls, fortified with several ramparts and bastions, eight yards high. The streets are handsome, and as straight as a line; but the houses are generally only one story high, on account of the earthquakes. However, they are pretty enough, and well adorned, having long galleries on the front. One part of the roofs are covered with coarse linen cloth, and the others only with reeds, which is not inconvenient, because it never rains here; however, the richest inhabitants cover theirs with fine mats or beautiful cotton-cloths. There are trees planted all round their houses, to keep off the heat of the sun. What the houses want in height they have in length and depth; for some of them are 200 feet long, and proportionably broad, so that they have 10 or 12 large apartments on the ground-floor. The royal square is very handsome, and in the middle there is a fountain of bronze, adorned with the image of Fame which spouts up water. On the east and west sides are the public structures, which are well built. The river which crosses Lima forms canals or streams which run to most of the houses, and serve to water their gardens, as well as for other uses. All the churches and convents are extremely rich; and many images of the saints are of massy gold, adorned with jewels. This city is four

Lilye,
Lima.

Lima.
Limaſſol

rules in length, and two in breadth, and is divided into eight parishes; and yet it contains but 28,000 inhabitants, whereof 9000 are Spaniards. They make use of mules to draw their coaches with, and of these there are about 5000. It is the seat of the viceroy, and contains several courts; as that of the viceroy, of the archbishop, of the inquisition, of the crusado, and of the wills. Earthquakes are here very frequent; some of which have done this city a great deal of damage, particularly that in 1746, whereby it was almost destroyed: were it not for this, it would be a perfect paradise; there being plenty of corn, wine, oil, sugar, fruits, and flax. The inhabitants are so rich, that when the viceroy, who was duke of Palata, and sent from Spain to Peru in 1672, made his public entrance into this city, the inhabitants paved the streets he was to pass through with ingots of silver. The inhabitants of Lima are very debauched, but at the same time extremely superstitious, and they have a strong belief in the power of charms. About a fourth part of the city are monks and nuns, who are not a jot more chaste than the rest; and if any one happens to rival a monk, he is in danger of his life, for they always carry a dagger under their frocks. The nuns are such libertines, that it is hard to find any free from the French disease, of which they sometimes die for want of good physicians. The greatest sinners think they atone for all their faults by hearing a mass, and kissing the robe of St Francis or St Dominic, and then they return to their former practices. It is seated on a large, pleasant, fertile plain, on a small river near the sea. W. Long. 68. 45. S. Lat. 12. 15.

Mariti's
Travels
through
Cyprus.

LIMASSOL, or LIMISSO, a town of Cyprus, in the south of the island. Of the ancient city nothing but ruins now remain; though it was a celebrated place, even under the government of the dukes. King Richard, the conqueror of the last of these vassals of the empire, razed it in 1191, and it was never afterwards rebuilt. This city originally was the same as AMATHUS, or AMATHONTE; so famous, as Pausanias tells us, for its temple erected in honour of Venus and Adonis. Amathus was the residence of the nine first kings of the island; and amongst others of Oneliftus, who was subjected afterwards by the arms of Artabanus, the Persian general. This city, erected into an archbishopric in the time of the Christians, has produced a number of personages celebrated for their knowledge and the sanctity of their lives. In the neighbourhood there are several copper mines, which the Turks have been forced to abandon. The following lines, in the tenth book of Ovid's *Metamorphoses*, prove that they were known in the time of that poet:

Capta viri forma, non jam Cytherea curat
Littora, non alio repetit Paphon aequore cinctam,
Piscosaneque Guidoni, gravidamque Amathus metallis.

The place where the new Limaſſol now stands, formerly had the name of *Nemofa*, from the multitude of woods by which it was surrounded. Richard king of England having destroyed Amathonte, Guy de Lusignan in the 12th century laid the foundations of that new city which the Greeks called *Neopolis*. The family of Lusignan, who continued to embellish and fortify it, built there palaces, and Greek and Latin churches; and made it the seat of a bishop. When the island was taken by the Turks in 1570, the Ot-

Lima.
Limb.

toman army entered this city on the 2d of July, and ravaged it without mercy. It was then destroyed by the flames; and at present it is only a wretched place, in which one can scarcely distinguish any remains of its ancient edifices. It is governed by a commissary and a cadi: the latter judges cases only provisionally, before they are carried to the superior tribunal of Nicotia. The harbour is very commodious; and being sheltered from impetuous winds, it affords a safe and calm asylum to vessels when overtaken by a storm. The carob-tree is here more abundant than any where else; and it is from the port of Limaſſol that the greatest quantity of its fruit is exported. The inhabitants export also salt, procured from a lake near Salines. Cotton, wheat, barley, and mulberry-trees, are both plentiful and well cultivated in this part of the island: the ground also produces all kinds of garden stuff. The best Cyprus wine is made from the vines that grow on the hills of Limaſſol. All the wines of the country are collected in this city to be transported to Larnci, where there are the largest cellars, and which on that account becomes the natural centre of commerce.

LIMAX, the *Slug*, or *Naked Snail*; a genus of insects belonging to the order of vermes mollusca. The body is oblong, fitted for crawling, with a kind of muscular coat on the upper part; and the belly is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure.—This reptile is always destitute of shell; but besides that its skin is more clammy and of a greater consistency than that of the snail, the black naked slug has a furrowed cloak, almost as thick and as hard as leather, under which it withdraws its head as within a shell. The head is distinguished from the breast by a black line. It is in its head and back that the snail-stone is found; which is a small pearly and sandy stone, of the nature of lime stones: according to a popular opinion, it cures the tertian ague, if fastened to the patient's arm. These slugs move on slowly, leaving every where clammy and shining marks of their passage. Their coming together is towards the end of spring. The organs of generation are placed, as in the snail, on the right side of the neck. The male implement unfolds with the same mechanism as the finger of a glove when turned inside out. They are sometimes met with hanging in the air with their heads downwards; and their tails, united by a kind of viscous and thick tie, grappled to the branch of a tree. In this situation they remain for three hours, and that is the time of impregnation. They deposit their eggs in the earth. There are eight species, distinguished entirely by their colour; as the black slug, the white slug, the reddish slug, the ash-coloured slug, &c. The black slug is hermaphrodite, both sexes being in each individual, and in the coitus both impregnate and are impregnated at the same time.—A black slug powdered over with snuff, salt, or sugar, falls into convulsions, casts forth all its foam, and dies. See REPRODUCTION.

LIMB, in general, denotes the border or edge of a thing; thus we say, the limb of a quadrant, of the sun, of a leaf, &c.

LIMB, in anatomy, an appellation given to the extremities of the body, as to the arms and legs.

LIMB, *Limbur*, in the church of Rome, is used in two different senses. 1. The limb of the patriarchs is

said to be the place where the patriarchs waited the redemption of mankind : in this place they suppose our Saviour's soul continued from the time of his death to his resurrection. 2. The limb of infants dying without baptism, is a place supposed to be distinct both from heaven and hell ; since, say they, children dying innocent of any actual sin, do not deserve hell ; and, by reason of their original sin, cannot be admitted into heaven.

LIMBAT, the name of a periodical wind common in the island of Cyprus, and of great service in moderating the heats of the climate, which would otherwise be intolerable.

According to the Abbé Mariti, it begins to blow at eight in the morning the first day ; increases as the sun advances till noon ; then gradually weakens, and at three falls entirely. On the second day it arises at the same hour ; but it does not attain its greatest strength till about one in the afternoon, and ceases at four precisely. On the third day it begins as before ; but it falls an hour later. On the five succeeding days, it follows the same progression as on the third ; but it is remarked, that a little before it ceases, it becomes extremely violent. At the expiration of five days it commences a new period like the former. By narrowly observing the sea on that side from which it is about to blow a little before it arises, one may determine what degree of strength it will have during the day. If the horizon is clear, and entirely free from clouds, the wind will be weak, and even almost insensible ; but if it is dark and cloudy, the wind will be strong and violent. This limbath wind, notwithstanding its utility in moderating the excessive heat, often becomes the cause of fevers, especially to the Europeans, from their being less habituated to the climate, more apt than the natives to suffer themselves to be surprized by the cool air when in a state of perspiration. This wind, the falling of which happens an hour sooner or later, is succeeded by a calm, accompanied by a certain moisture that renders the air somewhat heavy. This moisture disappears in the evening, being dissipated by a wind which arises every day at that period. This wind is considered as a land breeze by the inhabitants of the southern and eastern parts of the island ; but it is called a *sea breeze* by those in the northern and western, who indeed receive it immediately from the sea. In summer it blows till four o'clock in the morning ; and when it ceases, it leaves a profound calm, which continues till the hour when the limbath commences. In autumn and winter it never falls till day-break, when it is succeeded by other winds, which proceed from the irregularity of the season. In spring it does not continue longer than midnight ; and is then succeeded by that happy calm, during which those refreshing dews are formed that moisten the earth at sun-rising. The limbath winds, which arise in the beginning of summer, cease about the middle of September ; and this is the period when the most insupportable heats commence, because their violence is not moderated by the smallest breeze. They are, however, luckily not of long duration ; and about the latter end of October they decrease sensibly, as the atmosphere begins to be loaded with watery clouds.

LIMBORCH (Philip), a learned writer among the remonstrants, born at Amsterdam in 1633. After ha-

ving made great proficiency in his studies, he was, in 1655, admitted to preach in public, which he did first at Haerlem. His sermons had in them no affected cloquence ; but were solid, methodical, and edifying. He was chosen minister of Goudja ; from whence he was called to Amsterdam, where he had the professorship of divinity, in which he acquitted himself with great reputation till his death, which happened in 1712. He had an admirable genius, and a tenacious memory. He had many friends of distinction in foreign parts as well as in his own country. Some of his letters to Mr Locke are printed with those of that celebrated author. He had all the qualifications suitable to the character of a sincere divine, lived an example of every virtue, and preserved the vigour of his body and mind to a considerable age. He wrote many works, which are esteemed ; the principal of which are, 1. *Amica collatio de veritate religionis Christianae cum eruditio Judeo*, in 12mo. 2. A complete body of Divinity, according to the opinions and doctrines of the remonstrants. 3. A history of the Inquisition ; which has been translated into English by Dr Samuel Chandler. Limburch also published the works of the famous Episcopius, who was his great-uncle by the mother's side.

LIMBURGH-DUCHY, a province of the Austrian Netherlands, bounded by the duchy of Juliers on the north and east, by Luxembourg on the south, and by the bishopric of Liege on the west. It is about 30 miles in length, and 25 in breadth ; and consists of good arable and pasture land, with plenty of wood, and some iron mines.

LIMBURGH, the capital city of the duchy of Limburgh, in the Austrian Netherlands, is seated on a steep rock near the river Vesle. This town is small, but pleasantly seated on a hill, with shady woods ; and consists chiefly of one broad street, not very well built. It is strong by situation, and almost inaccessible ; however, it was taken by the French in 1675, and by the confederates under the duke of Marlborough in 1663, for the house of Austria, to whom it remains by the treaties of Rastadt and Baden, after having been dismantled. It is famous for its cheese, which is exceedingly good. E. Long. 6. 8. N. Lat. 50. 40.

LIMS, or **Lyme**. See **LYME**.

LIMERICK, a county of Ireland, in the province of Munster, is bounded on the east by Tipperary, on the west by Kerry, on the north by the river Shannon, and on the south by Cork. It is a fruitful and populous tract, the soil requiring little or no manure in most places : besides rich pasture for sheep and cows, it produces rich crops of all kinds of corn and rape, with some hemp. It gave title of earl to the family of Dongan. It contains 375,320 Irish plantation acres, about fifty-six church livings, though a much greater number of parishes, ten baronies, three boroughs, and sends eight members to parliament. It has some clays, furze, fern, and mountain lands, and is famous for good cyder ; it has been much benefited by the palatines, who settled there and increased tillage ; they are a laborious independent people, most-ly.

Limerick.

ly employed in their own farms. This country is well watered by large and small rivers; the Shannon runs at the north side of the county, and fertilizes its banks. The firing of the inhabitants is chiefly turf, and the bogs are conveniently situated. At Loughill in the west of the county, there is a mine of coal or culm, but it is more used in kilns than in houses. There are few lakes except Lough Gur; and the principal hills are Knockgreny, Knockany, Knockfiring, and Toryhill. The mountains lie weltward, the highest being Knockpatrick or St Patrick's hill. This county is about 45 miles long and 42 broad.

LIMERICK, or *Lough-Meath*, a market-town, a borough, and a bishop's see, now the metropolis of the province of Munster. It is situated on the river Shannon, 94 miles from Dublin; and was the strongest fortrefs in the kingdom. Its ancient name was Lunnach; and during the first ages it was much frequented by foreign merchants, and after the arrival of the Danes was a place of considerable commerce until the 12th century. It was plundered by Mahon, brother of Brien Boromh, after the battle of Sulchoid, in 970; and Brien, in a future period, exacted from the Danes of this city 365 tons of wine as a tribute, which shows the extensive traffic carried on by those people in that article. About the middle of the 6th century, St Munchin erected a church and founded a bishopric here; which, however, was destroyed by the Danes on their taking possession of this port in 873, and remained in ruins until their conversion to the Christian faith in the 10th century; at which period the church of St Munchin was rebuilt, and the bishopric established. Donald O'Brien, about the time of the arrival of the English, founded and endowed the cathedral; and Donat O'Brien, bishop of Limerick, in the 13th century, contributed much to the opulence of the see. About the close of the 12th century, the bishoprick of Innis-Cathay was united to that of Limerick. It was besieged by king William III. in the year 1690; and though there was no army to assist it, the king was obliged to raise the siege. In the year 1691, it was again besieged by the English and Dutch on the 21st of September; and it was obliged to surrender on the 13th of October following, not without the loss of abundance of men; however, the garrison had very honourable and advantageous conditions, being permitted to retire where they thought fit, and the Roman-catholics by these articles were to be tolerated in the free exercise of their religion. Within a century this place was reckoned the second city in Ireland; at present it has lost its rank; not because it thrives less, but because Cork thrives more. It is composed of the Irish and English town; the latter stands on the King's island, formed by the river Shannon. The town is three miles in circumference, having weekly markets on Wednesday and Saturday, and fairs on Easter Tuesday, 1st July, 4th August, and 12th December. There is a privilege annexed to the fair held on 4th August, that, during 15 days, no person can be arrested in the city or liberties, on any process issuing out of the Thollfel court of Limerick. Ardferit and Achadoe, in the county of Kerry, are united to the bishoprick of Limerick. This city returns two members to parliament; and gives title of viscount to the family of Hamilton. It is governed by a mayor, sheriffs, recorder,

aldermen, and burgeses; there is also a barrack and a military governor and town-major: it had some time the privilege of coinage; and different parliaments have been held there. The town was formerly entirely walled in; and in 1760, there were 17 of the city gates standing; but to the great improvement of the place they are now all demolished, except the water-gate of king John's castle. The linen, woollen, and paper manufactures, are carried on here to great extent, and the export of provisions is very considerable. Here are many charitable hospitals and handsome public buildings, besides the cathedral and other churches. A charter was granted to this city by king John, and confirmed in succeeding reigns. Dr Campbell observes, that as you approach Limerick, the grounds grow rich and exquisitely beautiful; the only disagreeable matter is, that the situation renders the air moist, and consequently rather unwholesome to strangers. About six miles from this is the famous Cattle-connel-spa. Limerick is 50 miles from Cork, 50 from Galway, and 73 from Waterford. It appears that Limerick obtained the privilege of having mayors 10 years before that right was allowed to the citizens of London. It was before governed by provosts, of which the first was John Spafford, in 1195 and 1197; during the provostship of Henry Troy a charter was granted, 9 Richard I. whereby the citizens were allowed to choose mayors and bailiffs, Adam Servant, in 1198, being the first mayor. It continued to be governed by mayors and bailiffs, until the office of bailiff was changed into that of sheriff, in 1609.

LIMERICK is also the name of a fair-town in the county of Wexford and province of Leinster; the fairs are four in the year.

LIMINGTON, a town of Hampshire in England. See LYMINGTON.

LIMIT, in a restrained sense, is used by mathematicians for a determined quantity to which a variable one continually approaches; in which sense, the circle may be said to be the limit of its circumscribed and inscribed polygons. In algebra, the term *limit* is applied to two quantities, one of which is greater and the other less than another quantity; and in this sense it is used in speaking of the limits of equations, whereby their solution is much facilitated.

LIMME, a town of Kent, in England, near Hithe, and four miles from Romney, was formerly a port, till choaked up by the sands; and though it is thereby become a poor town, yet it has the horn and mace and other tokens left of its ancient grandeur, and used to be the place where the lord warden of the cinqueports was sworn at his entrance upon his office. The Roman road from Canterbury, called *Stane-street*, ended here; and from the brow of its hill may be seen the ruinous Roman walls almost at the bottom of the marshes. Here formerly was a castle, now converted into a farm-house. When or by whom this edifice was erected is not known. It has, however, great marks of antiquity; as has also the adjoining church, in which are several old tombstones with crosses on them.

LIMNING, the art of painting in water-colours, in contradistinction to painting which is done in oil-colours.

Limning is much the more ancient kind of painting,

Limington
||
Limning.

Limning
||
Linacre.

ing. Till a Flemish painter, one John van Eyck, better known by the name of *John of Bruges*, found out the art of painting in oil, the painters all painted in water and in fresco, both on their walls, on wooden boards, and elsewhere. When they made use of boards, they usually glued a fine linen cloth over them, to prevent their opening; then laid on a ground of white; lastly, they mixed up their colours with water and size, or with water and yolks of eggs, well beaten with the branches of a fig-tree, the juice whereof thus mixed with the eggs; and with this mixture they painted their pieces.

In limning, all colours are proper enough, except the white made of lime, which is only used in fresco. The azure and ultramarine must always be mixed with size or gum; but there are always applied two layers of hot size before the size-colours are laid on: the colours are all ground in water each by itself; and, as they are required in working, are diluted with size-water. When the piece is finished, they go over it with the white of an egg well beaten; and then with varnish, if required.

To limn, or draw a face in colours: Having all the materials in readiness, lay the prepared colour on the card even and thin, free from hairs and spots over the place where the picture is to be. The ground being laid, and the party placed in a due position, begin the work, which is to be done at three sittings. At the first you are only to dead-colour the face, which will require about two hours. At the second sitting, go over the work more curiously, adding its particular graces or deformities. At the third sitting, finish the whole; carefully remarking whatever may conduce to render the piece perfect, as the cast of the eyes, moles, scars, gestures, and the like.

LIMOGES, an ancient and considerable town of France, in the province of Guienne, and capital of Limosin, with a bishop's see. It is a trading place, and its horses are in great esteem. It is seated on the river Vienne, in E. Long. 1. 22. N. Lat. 42. 48.

LIMOSIN, a province of France, bounded on the north by La Marche, on the east by Auvergne, on the south by Quercy, and on the west by Perigord and Angoumois. It is divided into the Upper and Lower; the former of which is very cold, but the latter more temperate. It is covered with forests of chefnut-trees; and contains mines of lead, copper, tin, and iron; but the principal trade consists in cattle and horses.

LIMPET. See PATELLA.

LIMPURG, a barony of Germany, in the circle of Franconia, included almost entirely within Suabia, and seated to the south of Hall in Suabia. It is about 15 miles long, and eight broad. Gaildorf and Shonburg, near which is the castle of Limpurg, are the principal places.

LIMPURG, a town of Germany, in the electorate of Trier or Treves, and in Wetteravia, formerly free and imperial, but now subject to the electorate of Treves. It is seated on the river Loha. E. Long. 8. 23. N. Lat. 50. 18.

LINARIA, in ornithology. See FRINGILLA.

LINACRE (Thomas), physician, was born at Canterbury about the year 1460, and there educated under the learned William Selling: thence he removed to Oxford, and in 1484 was chosen fellow of All-

Souls college. Tilly, *alias* Selling, his former instructor, being at this time appointed ambassador from King Henry VII. to the court of Rome, Mr Linacre accompanied him to Italy, where he attained the highest degree of perfection in the Greek and Latin languages. At Rome, he applied himself particularly to the study of Aristotle and Galen, in the original. On his return to Oxford, he was incorporated doctor of physic, and chosen public professor in that faculty. But he had not been long in England, before he was commanded to court by King Henry VII. to attend the young Prince Arthur as his tutor and physician. He was afterwards appointed physician to the king, and, after his death, to his successor Henry VIII. Dr Linacre founded two medical lectures at Oxford, and one at Cambridge; but that which most effectually immortalized his name among the faculty, is his being the first founder of the college of physicians in London. He beheld with vexation the wretched state of physic in those times; and, by an application to Cardinal Wolsey, obtained a patent in 1518, by which the physicians of London were incorporated. The intention of this corporation was to prevent illiterate and ignorant medicaliers from practising the art of healing. Dr Linacre was the first president, and held the office as long as he lived. Their meetings were in his own house in Knight-rider street, which house he bequeathed to the college. But our doctor, when he was about the age of 50, took it into his head to study divinity; entered into orders; and was collated, in 1509, to the rectory of Merham. In the same year he was installed prebendary of Wells, in 1518 prebendary of York, and in the following year was admitted precentor of that cathedral. This, we are told, he resigned for other preferments. He died of the stone in the bladder in October 1524, aged 64; and was buried in St Paul's. Thirty-three years after his death, Doctor John Caius caused a monument to be erected to his memory, with a Latin inscription, which contains the outlines of his life and character. He was a man of great natural sagacity, a skilful physician, a profound grammarian, and one of the best Greek and Latin scholars of his time. Erasmus in his epistles speaks highly of the doctor's translations from Galen, preferring them even to the original Greek. His works are, 1. *De emendata structura Latini sermonis, libri sex*; London, printed by Pynson, 1524, 8vo, and by Stephens, 1527, 1532. 2. The rudiments of grammar, for the use of the prince's Mary, printed by Pynson. Buchanan translated it into Latin; Paris, 1536. He likewise translated into very elegant Latin, several of Galen's works, which were printed chiefly abroad at different times. *Alfo Procli Diadochi sphaera*, translated from the Greek; Venet: 1499, 1500.

LINCOLN, a city of England, and capital of a county of the same name, is distant 132 miles from London. It stands on the side of a hill; at the bottom of which runs the river Withum in three small channels, over which are several bridges. The old *Lindum* of the Britons, which stood on the top of the hill, as appears from the vestiges of a rampart, and deep ditches still remaining, was taken and demolished by the Saxons; who built a town upon the south side of the hill down to the river side, which was several times.

Linacre,
Lincoln.

Lincoln.

times taken by the Danes, and as often retaken by the Saxons. In Edward the Confessor's time, it appears, from Doomday-book, to have been a very considerable place; and in the time of the Normans, Malmſbury ſays, it was one of the moſt populous cities in England. William I. built a caſtle upon the ſummit of the hill above the town. The dioceſe, though the biſhopric of Ely was taken out of it by Henry II. and thoſe of Peterborough and Oxford by Henry VIII. is ſtill vaſtly large, containing the counties of Leiceſter, Huntingdon, Bedford, and part of Bucks, making 1255 pariſhes. Though the other churches are mean, the cathedral or minſter is a moſt magnificent piece of Gothic architecture. Here is a prodigious large bell, called *Tom of Lincoln*, which is near five ton in weight, and 23 feet in compaſs. The hill on which the church ſtands is ſo high, and the church itſelf ſo lofty, that it may be ſeen 50 miles to the north, and 30 to the ſouth. Beſides other tombs, it contains one of braſs, in which are the entrails of Queen Eleaſor, wife to Edward I. It is ſaid there were anciently 52 churches, which are now reduced to 14. Such is the magnificence and elevation of the cathedral, that the monks thought the ſight of it muſt be very mortifying to the devil; whence it came to be ſaid of one who was diſpleaſed, *that he looked like the devil over Lincoln*. The declivity on which the city is built being ſteep, the communication betwixt the upper and lower town is very troubleſome, and coaches and horſes are obliged to make a compaſs.

King Edward III. made this city a ſtaple for wool, leather, lead, &c. It was once burnt; once beſieged by King Stephen, who was here defeated and taken priſoner; and once taken by Henry III. from his rebellious barons. It abounded heretofore with monaſteries and other religious houſes. There is a great pool here, formed by the river on the weſt ſide of it, called *Swan-Pool*, becauſe of the multitude of ſwans on it. The Romans north gate ſtill remains entire, by the name of *Newport-Gate*. It is one of the nobleſt of this fort in Britain. It is a vaſt ſemicircle of ſtones of very large dimensions laid without mortar, connected only by their uniform ſhape. This magnificent arch is 16 feet in diameter, the ſtones are four feet thick at the bottom. It ſeems to have a joint in the middle, not a key-ſtone; and on both ſides, towards the upper part, are laid horizontal ſtones of great dimensions, ſome 10 or 12 feet long. This arch riſes from an impoſſible large mouldings, which are not perceivable now; there are alſo divers fragments of the old Roman wall. Over againſt the caſtle is an entrenchment caſt up by king Stephen; and here are carved the arms of John of Gaunt, duke of Lancaſter, who lived here like a king, and had a mint. The city has a communication with the Trent, by a canal called the *Foſs-dyke*. In the centre of the ruined old caſtle there is a handſome modern ſtructure for holding the aſſizes. Its walls are almoſt entire, and very ſubſtantial: the Keep or principal tower is ſituated on a high and very ſteep mount, which yet continues in its original ſtate, but the remains of the tower on it are only five or fix yards high. The outer walls of the caſtle are of very conſiderable height, which appear ſtill higher than they really are from their lofty ſituation and the moat below them. The great gateway is ſtill entire. This city

Lincoln.

is a county of itſelf, and has a viſcountial juriſdiction for 20 miles round, which is a privilege that no other city in England can equal. It now conſiſts principally of one ſtreet above two miles long, well paved, beſides ſeveral croſs and parallel ſtreets well peopled. Here are ſome very handſome modern buildings, but more antique ones; upon the whole, it has an air of ancient greatneſs, ariſing in a great meaſure from the number of monaſtic remains, moſt of which are now converted into ſtables, out-houſes, &c. Upon the hill, in the caſtle are the ruins of the biſhop's palace, and other ruins of ancient grandeur and magnificence. The city is ſupplied with water by ſeveral conduits, among which is a modern one, ſomewhat in the pyramidal ſtyle, enriched with ſculpture. It is governed by a mayor, twelve aldermen, two ſheriffs, a recorder, four chamberlains, a ſword-bearer, four coroners, and above forty common-council men. Here are four charity ſchools, where 120 poor children are taught by the widows of clergymen. The neighbouring courſe is noted for its frequent horſe-races. On the down of Lincoln, towards Boſton, that rare fowl the bultard is ſeen ſometimes, as well as on Saluſbury-Plain. Lincoln-Heath extends above 50 miles, viz. from Sleaford and Ancaſter ſouth to the Humber north, though it is but three or four miles over where broadest. Five miles from Boſton on this extenſive heath, the late Lord Le Deſpenſer built a few years ago a tower for the direction of ſtrangers. It is a lofty ſquare building with a ſtair-caſe, which terminates in a flat roof, and round the baſe is a ſquare court-yard. Great part of this extenſive heath is lately incloſed. The markets here are Tueſdays and Fridays; and there are four fairs in the year. We read that David king of Scots met king John here, on the 22d of November, in the third year of his reign, and performed homage to him on a hill without the city, for his Engliſh territories, in preſence of the archbiſhops of Canterbury, York, and Ragufa, 13 biſhops, and a vaſt number of temporal lords and knights. King Henry VII. kept his court here at Eaſter in 1486. The Jews were once its chief inhabitants, till they were forced to remove, after having impiouſly crucified the child of one Grantham, and thrown it into a well, to this day called *Grantham's Well*. Lincoln has given the title of earl to the family of Clinton ever ſince the reign of Queen Elizabeth. W. Long. 27. 1. N. Lat. 53. 16.

LINCOLN-Shire, a maritime county of England, 77 miles in length and 48 in breadth, is bounded on the eaſt by the German ocean, on the weſt by Nottinghamſhire, on the north by Yorkſhire, on the ſouth by Rutlandſhire, Northamptonſhire, and Cambridgeſhire. It contains 4590 houſes, 24,340 inhabitants, 631 pariſhes, and 31 market towns, whereof five ſend members to parliament, which, with two for the county, make twelve in all. The principal rivers are the Humber, the Trent, the Witham, the Nene, the Welland, the Ankhram, and the Don. It is divided into three parts, Linſay, Keſtoven, and Holland; the air of which laſt is unwholeſome and foggy, on account of the ſens and large marſhes. The ſoil of the north and weſt parts is very fertile, and abounds in corn and paſtures. The eaſt and ſouth parts are not ſo proper for corn; but then they ſupply them with fiſh and fowl in great plenty, particularly ducks and geefe. Lincoln

Lincolnshire is the principal town. By the late inland navigation, this county has communication with the rivers Mersey, Dee, Ribble, Ouse, Darwent, Severn, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles through diverse counties.

LINDESFARN, or **LANDISFARN**. See *HOLM-Jland*.

LINDSAY (Sir David), a celebrated Scots poet, was descended of an ancient family, and born in the reign of king James IV. at his father's seat called the *Mount*, near Cupar in Fifeshire. He was educated at the university of St Andrew's; and, after making the tour of Europe, returned to Scotland in the year 1514. Soon after his arrival, he was appointed gentleman of the bed-chamber to the king, and tutor to the young prince, afterwards James V. From the verses prefixed to his dream, we learn that he enjoyed several other honourable employments at court: but, in 1533, he was deprived of all his places, except that of *Lion king at arms*, which he held to the time of his death. His disgrace was most probably owing to his invectives against the clergy, which are frequent in all his writings. After the decease of king James V. Sir David became a favourite of the earl of Arran, regent of Scotland; but the abbot of Paisley did not suffer him to continue long in favour with the earl. He then retired to his paternal estate, and spent the remainder of his days in rural tranquillity. He died in the year 1553. His poetical talents, considering the age in which he wrote, were not contemptible; but he treats the Romish clergy with great severity, and writes with some humour: but, whatever merit might be formerly attributed to him, he takes such licentious liberties with words, stretching, or carving them for measure or rhyme, that the Scots have a proverb, when they hear an unusual expression, that, *There is nae sic a word in a' Davie Lindsay*. Mackenzie tells us, that his comedies were so facetious, that they afforded abundance of mirth. Some fragments of these comedies are still preserved in manuscript. He is said to have also written several tragedies, and to have first introduced dramatic poetry into Scotland. One of his comedies was played in 1515. Mackenzie says, he understood nothing of the rules of the theatre. He was cotemporary with John Heywood, the first English dramatic poet. His poems are printed in one small volume; and fragments of his plays, in manuscript, are in Mr William Carmichael's collection.

LINDSEY, the third and largest division of the county of Lincolnshire in England. On the east and north it is washed by the sea, into which it runs out with a large front; on the west it has Yorkshire and Nottinghamshire, from which it is parted by the rivers Trent and Dun; on the south it has Kesteven, from which it is separated by the river Witham and the Foss-dyke, which is seven miles long, and was cut by Henry I. between the Witham and the Trent, for the convenience of carriage in those parts. It had its name from Lincoln, the capital of the county, which stands in it, and by the Romans called *Lindum*, by the Britons *Lindcoln*, by the Saxons *Lindo-colligne*, probably from its situation on a hill, and the lakes or woods that were anciently thereabouts; but the Normans called it *Nicol*. It gives title of earl and marquis to the duke of Ancaffer.

VOL. X. Part L

LINDUS, (anc. geog.), a town of Rhodes, situated on a hill on the west side of the island. It was built by Tlepolemus the son of Hercules, according to Diodorus Siculus; by one of the Heliades, grandsons of the Sun, named *Lindus*, according to Strabo. It was the native place of Cleobulus, one of the wise men. Here we see the famous temple of Lindian Minerva, which was built by the daughters of Danaus. Cadmus enriched this temple with many splendid offerings. The citizens dedicated and hung up here the seventh of Pindar's Olympic odes, written in letters of gold. The ruins of that superb edifice are still to be seen on the top of an high hill which overlooks the sea. Some remains of the walls, consisting of stones of an enormous size, still show it to have been built in the Egyptian style. The pillars and other ornaments have been carried off. On the most elevated peak of the rock are the ruins of a castle, which may have served as a fortress to the city. Its circumference is very extensive, and is filled with rubbish.

Lindo, the modern city, stands at the foot of the hill. A bay, of considerable wideness and depth, serves as a harbour to the city. Ships find good anchorage there in twenty fathoms water. They are safely sheltered from the south-west winds, which constantly prevail through the severest season of the year. In the beginning of winter, they cast anchor off a small village named Maffary. Before the building of Rhodes, Lindus was the harbour which received the fleets of Egypt and Tyre. It was enriched by commerce. Mr Savary observes, that a judicious government, by taking advantage of its harbour and happy situation, might yet restore it to a flourishing state.

LINE, in geometry, a quantity extended in length only, without any breadth or thickness. It is formed by the flux, or motion of a point. See *FLUXIONS*, and *GEOMETRY*.

LINE, in the art of war, is understood of the disposition of an army ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

LINE of Battle, is also understood of a disposition of the fleet in the day of engagement; on which occasion the vessels are usually drawn up as much as possible in a straight line, as well to gain and keep the advantage of the wind as to run the same board. See *Naval TACTICS*.

HORIZONTAL LINE, in geography and astronomy, a line drawn parallel to the horizon of any part of the earth.

EQUINOCTIAL LINE, in geography, is a great circle on the earth's surface, exactly at the distance of 90° from each of the poles, and of consequence bisecting the earth in that part. From this imaginary line, the degrees of longitude and latitude are counted.—In astronomy, the equinoctial line is that circle which the sun seems to describe round the earth on the days of the equinox in March and September. See *ASTRONOMY* and *GEOGRAPHY*.

MERIDIAN LINE, is an imaginary circle drawn thro' the two poles of the earth and any part of its surface. See *GEOGRAPHY*, n° 29.

SHIP of the LINE, a vessel large enough to be drawn up in the line, and to have a place in a fight.

L

LINE,

Lindus, Line.

LINE, in genealogy, a series or succession of relations in various degrees, all descending from the same common father. See DESCENT.

LINE, also denotes a French measure containing the 12th part of an inch, or the 144th part of a foot. Geometricians conceive the line subdivided into fix points. The French line answers to the English barley-corn.

Fishing LINE. See *FISHING LINE*.

LINEs, in heraldry, the figures used in armories to divide the shield into different parts, and to compose different figures. / These lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines. See HERALDRY.

LINEA ALBA, in anatomy, the concourse of the tendons of the oblique and transverse muscles of the abdomen; dividing the abdomen in two, in the middle. It is called *linea*, line, as being straight; and *alba*, from its colour, which is white.—The *linea alba* receives a twig of a nerve from the intercostals in each of its digitations or indentings, which are visible to the eye, in lean persons especially.

LINEAMENT, among painters, is used for the outlines of a face.

LINEAR NUMBERS, in mathematics, such as have relation to length only; such is a number which represents one side of a plain figure. If the plain figure be a square, the linear figure is called a *root*.

LINEAR Problem; that which may be solved geometrically by the intersection of two right lines. This is called a *simple problem*, and is capable but of one solution.

LINEN, in commerce, a well-known kind of cloth chiefly made of flax.—Linen was not worn by the Jews, Greeks, or Romans, as any part of their ordinary dress. Under tunicks of a finer texture supplied the place of shirts: Hence the occasion for frequent bathing. Alexander Severus was the first emperor who wore a shirt: but the use of so necessary a garment did not become common till long after him.

The linen manufacture was probably introduced into Britain with the first settlements of the Romans. The flax was certainly first planted by that nation in the British soil. The plant itself indeed appears to have been originally a native of the east. The woollen drapery would naturally be prior in its origin to the linen; and the fibrous plants from which the threads of the latter are produced, seems to have been first noticed and worked by the inhabitants of Egypt. In Egypt, indeed, the linen manufacture appears to have been very early: for even in Joseph's time it had risen to a considerable height. From the Egyptians the knowledge of it proceeded probably to the Greeks, and from them to the Romans. Even at this day the flax is imported among us from the eastern nations; the western kind being merely a degenerate species of it.

In order to succeed in the linen manufacture, one set of people should be confined to the ploughing and preparing the soil, sowing and covering the seed, to the weeding, pulling, rippling, and taking care of the new seed, and watering and dressing the flax till it is lodged at home: others should be concerned in

the drying, breaking, scutching, and heckling the flax, to fit it for the spinners; and others in spinning and reeling it, to fit it for the weaver: others should be concerned in taking due care of the weaving, bleaching, beetling, and finishing the cloth for the market. It is reasonable to believe, that if these several branches of the manufacture were carried on by distinct dealers in Scotland and Ireland, where our home-made linens are manufactured, the several parts would be better executed, and the whole would be afforded cheaper, and with greater profit.

Staining of LINEN. Linen receives a black colour with much more difficulty than woollen or cotton. The black struck on linen with common vitriol and galls, or logwood, is very perishable, and soon washes out.—Instead of the vitriol, a solution of iron in four strong beer is to be made use of. This is well known to all the calico-printers; and by the use of this, which they call their *iron liquor*, and madder-root, are the blacks and purples made which we see on the common printed linens. The method of making this iron-liquor is as follows: A quantity of iron is put into the four strong beer; and, to promote the dissolution of the metal, the whole is occasionally well stirred, the liquor occasionally drawn off, and the rust beat from the iron, after which the liquor is poured on again. A length of time is required to make the impregnation perfect; the solution being reckoned unfit for use till it has stood at least a twelvemonth. This solution stains the linen of a yellow, and different shades of buff-colour; and is the only known substance by which these colours can be fixed on linen. The cloth stained deep with the iron liquor, and afterwards boiled with madder, without any other addition, becomes of the dark colour which we see on printed linens and cottons; which, if not a perfect black, has a very near resemblance to it. Others are stained paler with the same liquor diluted with water, and come out purple.

Linen may also be stained of a durable purple by means of solution of gold in aqua regia. The solution for this purpose should be as fully saturated as possible; it should be diluted with three times its quantity of water; and if the colour is required deep, the piece, when dry, must be repeatedly moistened with it. The colour does not take place till a considerable time, sometimes several days, after the liquor has been applied: to hasten its appearance, the subject should be exposed to the sun and free air, and occasionally removed to a moist place, or moistened with water.—When solution of gold in aqua regia is soaked up in linen cloths, the metal may be recovered by drying and burning them.

The anacardium nut, which comes from the East-Indies, is remarkable for its property of staining linen of a deep black colour, which cannot be washed out either with soap or alkaline ley. The stain is at first of a reddish-brown, but afterwards turns to a deep black on exposure to the air. The cashew-nut, called the *anacardium of the West-Indies*, differs from the oriental anacardium in its colouring quality. The juice of this nut is much paler than the other, and stains linen or cotton only of a brownish colour; which indeed is very durable, but does not at all change towards blackness.—There are, however, trees, natives of our own colonies, which appear to contain juices of the same

Lin. fame nature with those of India. Of this kind are several, and perhaps the greater number, of the species of the toxicodendron or poison-tree †. Mr Catesby, in his history of Carolina, describes one called there the *poison-ash*, from whose trunk flowed a liquid as black as ink, and supposed to be poisonous; which reputed poisonous quality has hitherto prevented the inhabitants from collecting or attempting to make any use of it. In the Philosophical Transactions for the year 1755, the abbé Mazeas gives an account of three sorts of the toxicodendron raised in a botanic garden in France, containing in their leaves a milky juice, which in drying became quite black, and communicated the same colour to the linen on which it was dropped. The linen thus stained was boiled with soap, and came out without the least diminution of colour; nor did a strong ley of wood-ashes make any change in it. Several of these trees have been planted in the open ground in England, and some still remain in the bishop of London's garden at Fulham.

That species called by Mr Miller the *true lac tree*, was found by Dr Lewis to have properties of a similar kind. It contains in its bark, and the pedicles and ribs of the leaves, a juice somewhat milky, which soon changed in the air to a reddish-brown, and in two or three hours to a deep blackish or brownish-black colour; wherever the bark was cut or wounded, the incision became blackish; and on several parts of the leaves the juice had spontaneously exuded, and stained them of the same colour. This juice dropped on linen gave at first little or no colour, looking only like a spot of oil; but, by degrees, the part moistened with it darkened in the same manner as the juice itself. On washing and boiling the linen with soap, the stain not only was not discharged, but seemed to have its blackness rather improved; as if a brown matter, with which the black was manifestly debased, had been in part washed out, and left the black more pure.

As the milky juice of some of our common plants turn dark-coloured or blackish in drying, the Doctor was induced to try the effects of several of them on linen. The milks of wild-poppies, garden-poppies, dandelion, hawk-weed, and fow-thistle, gave brown or brownish-red stains, which were discharged by washing with soap; the milks of the fig-tree, of lettucees, and of different kinds of spurgees, gave no colour at all. The colourless juice which issues from hop-stalks when cut, stains linen of a pale-reddish, or brownish-red, extremely durable; the colour was deepened by repeated applications of the juice, but it never made any approach to blackness. The juice of flocks gave likewise a pale-brownish stain, which by repeated washings with soap, and being wetted with strong solution of alkaline salt, was darkened to a deeper brown: on baking the flocks, their juice turns red; and the red stain which it then imparts to linen is, on washing with soap, changed to a pale-bluish, which also proves durable. These colours could not be deepened by repeated applications of the juice. The flocks were tried in different states of maturity, from the beginning of September to the middle of December, and the event was always nearly the same.

In the fifth volume of Linnæus's *Amenitates Academicæ*, mention is made of a black colour obtained from

two plants which grow spontaneously in Britain; the one is the *adæa spicata*, herb-christopher, or bane-berries; the other the *erica baccifera nigra*, black-berried heath, crow-berries, or crane-berries. The juice of the bane-berries, boiled with alum, is said to yield a black ink; and the heath-berries, boiled also with alum, to dye linen of a purplish black.

LINEN flowered with Gold-leaf. Dr Lewis informs us of a late manufacture established in London for embellishing linen with flowers and ornaments of gold-leaf. The linen, he says, looks whiter than most of the printed linens; the gold is extremely beautiful, and bears washing well. The Doctor informs us, that he had seen a piece which he was credibly informed had been washed three or four times, with only the same precautions which are used for the finer printed linens; and on which the gold continued entire, and of great beauty.—Concerning the process used in this manufacture, he gives us no particulars.

Fossile LINEN, is a kind of amianthus, which consists of flexible, parallel, soft fibres, and which has been celebrated for the uses to which it has been applied, of being woven, and forming an *incumbustible cloth*. Paper alo, and wicks for lamps, have been made of it. See AMIANTHUS and ASBESTOS.

LING, in zoology. See GADUS.

LINGEN, a strong town of Germany, in the circle of Westphalia, and capital of a county of the same name. It belongs to the king of Prussia; and is situated on the river Embs, in E. Long. 7. 30. N. Lat. 52. 32.

LINGELBACH (John), an excellent painter, born at Franckfort on the Maine in 1625. He first learned the art in Holland, but perfected himself at Rome; where he studied till he was 25 years of age, when he settled at Amsterdam. His usual subjects are fairs, mountebanks, sea-pieces, and landscapes, which he composed and executed exceeding well: his landscapes are enriched with antiquities, animals, and elegant figures; his sea-sights are full of expression, exciting pity and terror, and all his objects are well designed. He had an uncommon readiness in painting figures and animals, on which account he was employed by several eminent artists to adorn their landscapes with such objects; and whatever he inserted in the works of other masters, were always well adapted, and produced an agreeable effect. He died in 1687.

LINIMENT, in pharmacy, a composition of a consistence somewhat thinner than an unguent, and thicker than an oil used for anointing different parts of the body in various intentions.—The materials proper for composing liniments are, fats, oil, balsams, and whatever enters the composition of unguents and plasters.

LINLITHGOW, the chief town of West Lothian in Scotland. It is supposed to be the *Lindum* of Ptolemy; and to take its name from its situation on a lake, which the word *Lin* or *Llyn* signifies.—It is distant 16 miles from Edinburgh, and is a royal borough and feat of a presbytery. It contains between three and four thousand souls; and carries on a considerable trade in dressing of white leather, which is sent abroad to be manufactured. It also employs many hands in dressing of flax; also in wool-combing, the wool for which is brought

Ling
||
Linlithgow.

Linlithgow,
Linnaeus.

brought from the borders. Its port was formerly *Blacknefs*; but since the decline of that place, *Burrowslounnefs*, about two miles diftant from Linlithgow. The town confifts of one open ftreet, from whence lanes are detached on both fides; the houfes are built of ftone, tolerably neat and commodious; and the place is adorned with fome ftately public edifices. The palace, built, as Sibbald fuppofed, on the fite of a Roman ftation, forms a fquare with towers at the corners, and ftands on a gentle eminence, with the beautiful loch behind it to the weft. It was one of the nobleft of the royal refidences; and was greatly ornamented by James V. and VI. Within the palace is a handfome fquare; one fide of which is more modern than the others, having been built by James VI. and kept in good repair till 1746, when it was accidentally damaged by the king's forces making fires on the hearths, by which means the joifts were burnt. A ftone ornamented fountain in the middle of the court was deftroyed at the fame time. The other fides of the fquare are more ancient. In one is a room ninety-five feet long, thirty feet fix inches wide, and thirty-three high. At one end is a gallery with three arches, perhaps for mufic. Narrow galleries run quite round the old part, to preferve communications with the rooms; in one of which the unfortunate Mary Stuart firft faw light. On the north fide of the high ftreet, on an eminence eaft of the palace, ftands St Michael's church; a handfome ftructure, where James V. intended to have erected a throne and twelve ftalls for the fovereign and knights of the order of St Andrew. In the market-place is another fountain of two ftories with eight fpouts, and furmounted like the former with an imperial crown. In one of the ftreets is fhown the gallery whence the regent Murray was fhot. Here was a houfe of Carmelites, founded by the townfpeople in 1290, deftroyed by the reformers 1559. The family of Livingfton, who take the title of earl from this place, are hereditary keepers of this palace, as alfo bailiffs of the king's bailiury, and conftables of Blacknefs caftle; but by their concern in the rebellion of 1715 all thefe honours with their eftate were forfeited to the crown. Sir James Livingfton, fon of the firft earl by marriage with a daughter of Callendar, was created earl of Callendar by Charles I. 1641, which title funk into the other.

LINNEÆUS (Sir Charles), a celebrated botanift and natural hiftorian, was born on May 24. 1707, in a village called *Rofholt* in Smaland, where his father, Nicolas Linnaeus, was then vicar, but afterwards preferred to the curacy of Stenbrohult. We are told, that on the farm where Linnaeus was born, there yet ftands a large lime-tree, from which his anceftors took the furnames of *Tilander*, *Lindelius*, and *Linnaeus*; and that this origin of furnames, taken from natural objects, is not uncommon in Sweden.

This eminent man, whose talents enabled him to reform the whole fciences of natural hiftory, accumulated, very early in life, fome of the higheft honours that await the moft fucceffful proficients in medical fciences; fince we find that he was made profeffor of phyfic and botany, in the univerfity of Upfal, at the age of 34; and fix years afterwards, phyfician to his fovereign the late king Adolphus; who in the year 1753 honoured him ftill farther, by creating him knight of the order of the Polar Star. His honours did not terminate here: for in 1757 he was ennobled; and in 1776 the

prefent king of Sweden accepted the refignation of his office, and rewarded his declining years by doubling his penfion, and by a liberal donation of landed property fettled on him and his family.

It feems probable, that Linnaeus's tafte for the ftudy of nature was caught from the example of his father; who, as he has himfelf informed us, cultivated, as his firft amufement, a garden plentifully ftored with plants. Young Linnaeus foon became acquainted with thefe, as well as with the indigenous ones of his neighbourhood. Yet, from the ftrainings of his father's income, our young naturalift was on the point of being deftined to a mechanical employment: fortunately, however, this defign was over-ruled. In 1717 he was fent to fchool at Wexfio; where, as his opportunities were enlarged, his progrefs in all his favourite purfuits was proportionably extended. At this early period he paid attention to other branches of natural hiftory, particularly to the knowledge of infects.

The firft part of his academical education Linnaeus received under profeffor Stobæus, at Lund, in Scania, who favoured his inclinations to the ftudy of natural hiftory. After a refidence of about a year, he removed in 1728 to Upfal. Here he foon contracted a clofe friendship with Artedi, a native of the province of Angermania, who had already been four years a ftudent in that univerfity, and, like himfelf, had a ftrong bent to the ftudy of natural hiftory in general, but particularly to ichthyology. Soon after his refidence at Upfal, our author was alfo happy enough to obtain the favour of feveral gentlemen of eftablifhed character in literature. He was in a particular manner encouraged in the purfuit of his ftudies by the patronage of Dr Olaus Celfius, at that time profeffor of divinity, and the reftorer of natural hiftory in Sweden; who, being ftruck with the diligence of Linnaeus in defcribing the plants of the Upfal garden, and his extenfive knowledge of their names, not only patronized him in a general way, but admitted him to his houfe, his table, and his library. Under fuch encouragement it is not ftrange that our author made a rapid progrefs, both in his ftudies and the efteem of the profeffors: in fact, we have a very ftriking proof of his merit and attainments, inafmuch as we find, that, after only two years refidence, he was thought fufficiently qualified to give lectures occasionally from the botanic chair, in the room of profeffor Rudbeck.

In the year 1731, the royal academy of fciences at Upfal having for fome time meditated the defign of improving the natural hiftory of Sweden, at the inftance particularly of profefors Celfius and Rudbeck, deputed Linnaeus to make the tour of Lapland, with the fole view of exploring the natural hiftory of that arctic region; to which undertaking, his reputation, already high as a naturalift, and the ftrength of his conftitution, equally recommended him. He left Upfal the 13th of May, and took his route to Gevalia or Gevels, the principal town of Geltricia, 45 miles diftant from Upfal. Hence he travelled through Helſingland into Medlapadia, where he made an excursion, and afcended a remarkable mountain, before he reached Hudwickſwald, the chief town of Helſingland. From hence he went through Angermanland to Hernofand, a fea-port on the Bothnic gulf, 70 miles diftant from Hudwickſwald. When he had proceeded thus far, he found it proper to re-
tard

Linnaeus.

Pultney's
General
View of the
Life and
Writings of
Linnaeus.

Linneus.

tard his journey, as the spring was not sufficiently advanced; and took this opportunity of visiting those remarkable caverns on the summit of mount Skula, though at the hazard of his life.

When Linnæus arrived at Uma, in West Bothnia, about 96 miles from Hernofand, he quitted the public road, and took his course through the woods westward, in order first to traverse the most southern parts of Lapland. Being now come to the country that was more particularly the object of his inquiries, equally a stranger to the language and to the manners of the people, and without any associate, he committed himself to the hospitality of the inhabitants, and never failed to experience it fully. He speaks in several places, with peculiar satisfaction, of the innocence and simplicity of their lives and their freedom from diseases. In this excursion he reached the mountains towards Norway; and, after encountering great hardships, returned into West Bothnia, quite exhausted with fatigue. Our traveller next visited Pitha and Lula, upon the gulf of Bothnia; from which latter place he took again a western route, by proceeding up the river of that name, and visited the ruins of the temple of Jockmook in Lula Lapland or Lap Mark; thence he traversed what is called the *Lapland Desert*, destitute of all villages, cultivation, roads, or any conveniences; inhabited only by a few straggling people, originally descended from the Finlanders, and who settled in this country in remote ages, being entirely a distinct people from the Laplanders. In this district he ascended a noted mountain called *Wallevari*; in speaking of which he has given us a pleasant relation of his finding a singular and beautiful new plant (*Andromeda tetragona*) when travelling within the arctic circle, with the sun in his view at midnight, in search of a Lapland hut. From hence he crossed the Lapland Alps into Finmark, and traversed the shores of the north sea as far as Sallero.

These journeys from Lula and Pitha on the Bothnian gulf, to the north shore, were made on foot; and our traveller was attended by two Laplanders, one his interpreter, and the other his guide. He tells us, that the vigour and strength of those two men, both old, and sufficiently loaded with his baggage, excited his admiration; since they appeared quite unhurt by their labour, while he himself, although young and robust, was frequently quite exhausted. In this journey he was wont to sleep under the boat with which they forded the rivers, as a defence against rain, and the gnats, which in the Lapland summer are not less teasing than in the torrid zones. In defending one of these rivers, he narrowly escaped perishing by the oversetting of the boat, and lost many of the natural productions which he had collected.

Linnæus thus spent the greater part of the summer in examining this arctic region, and those mountains on which, four years afterwards, the French philosophers secured immortal fame to Sir Isaac Newton. At length, after having suffered incredible fatigues and hardships in climbing precipices, passing rivers in miserable boats, suffering repeated vicissitudes of extreme heat and cold, and not unfrequently hunger and thirst, he returned to Tornaa in September. He did not take the same route from Tornaa as when he came into Lapland, having determined to visit and examine

Linneus.

the country on the eastern side of the Bothnian gulf; his first stage, therefore, was to Ula in East Bothnia; from thence to Old and New Carleby, 84 miles south from Ula. He continued his route through Wafsa, Christianfadt, and Biornburgh, to Abo, a small university in Finland. Winter was now setting in apace; he therefore crossed the gulf by the island of Åland, and arrived at Upfal in November, after having performed, and that mostly on foot, a journey of ten degrees of latitude in extent, exclusively of those deviations which such a design rendered necessary.

In 1733 he visited and examined the several mines in Sweden; and made himself so well acquainted with mineralogy and the docimastic art, that we find he was sufficiently qualified to give lectures on those subjects upon his return to the university. The outlines of his system on mineralogy appeared in the early editions of the *Systema Nature*; but he did not exemplify the whole until the year 1768.

In the year 1734 Linnæus was sent by baron Reuterholm governor of Dalekaria, with several other naturalists in that province, to investigate the natural productions of that part of the Swedish dominions; and it was in this journey that our author first laid the plan of an excellent institution, which was afterwards executed, in a certain degree at least, by himself, with the assistance of many of his pupils, and the result published under the title of *Pan Suecus*, in the second volume of the *Amnities Academicæ*.

After the completion of this expedition, it appears that Linnæus resided for a time at Fahlun, the principal town in Dalekaria; where he tells us, that he taught mineralogy and the docimastic art, and practised physic; and where he was very hospitably treated by Dr More, the physician of the place. It also appears, that he contracted at this time an intimacy with one of that gentleman's daughters, whom he married about five years afterwards upon his settling as a physician at Stockholm.—In this journey he extended his travels quite across the Dalekarian Alps into Norway; but we have no particular account of his discoveries in that kingdom. In 1735 Linnæus travelled over many other parts of Sweden, some parts of Denmark and Germany, and fixed in Holland, where he chiefly resided until his return to Stockholm, about the year 1739. In 1735, the year in which he took the degree of M. D. he published the first sketch of his *Systema Nature*, in a very compendious way, and in the form of tables only, in 12 pages in folio. By this it appears, that he had at a very early period of his life (certainly before he was 24 years old) laid the basis of that great structure which he afterwards raised, not only to the increase of his own fame, but to that of natural science.

In 1736, Linnæus came into England, and visited Dr Dillenius, the late learned professor at Oxford, whom he justly considered as one of the first botanists in Europe. He mentions with particular respect the civilities he received from him, and the privileges he gave him of inspecting his own and the Sherardian collections of plants. It is needless to say, that he visited Dr Martyn, Mr Rand, and Mr Miller, and that he was in a more singular manner indebted to the friendship of Dr Isaac Lawson. He also contracted an intimate friendship with Mr Peter Collinson, which was reciprocally increased by a multitude

Linnaeus, titude of good offices, and continued to the last without any diminution. Dr Boerhaave had furnished him with letters to our great naturalist Sir Hans Sloane; but, it is with regret that we must observe, they did not procure him the reception which the warmth of his recommendation seemed to claim.

One of the most agreeable circumstances that happened to Linnæus during his residence in Holland, arose from the patronage of Mr Clifford, in whose house he lived a considerable part of his time, being now as it were the child of fortune:—*Exivi patriâ triginta sex nummis aureis dives*—are his own words. With Mr Clifford, however, he enjoyed pleasures and privileges scarcely at that time to be met with elsewhere in the world; that of a garden, excellently stored with the finest exotics, and a library furnished with almost every botanic author of note. How happy he found himself in this situation, those only who have felt the same kind of ardour can conceive. Whilst in Holland, our author was recommended by Boerhaave to fill the place, then vacant, of physician to the Dutch settlement at Surinam; but he declined it on account of his having been educated in so opposite a climate.

Besides being favoured with the particular patronage and friendship of Boerhaave and Mr Clifford, as is above mentioned, our author had also the pleasure of being contemporary with, and of reckoning among the number of his friends, many other learned persons who have since proved ornaments to their profession, and whose merit has most deservedly raised them to fame and honour. Among these we may properly mention Dr John Burman, professor of botany at Amsterdam, whose name and family are well known in the republic of letters, and to whom our author dedicated his *Bibliotheca Botanica*, having been greatly assisted in compiling that work by the free access he had to that gentleman's excellent library; John Frederick Gronovius of Leyden, editor of Clayton's *Flora Virginica*, and who very early adopted Linnæus's system; Baron Van Swieten, late physician to the Empress Queen; Isaac Lawfon, before mentioned, afterwards one of the physicians to the British army, who died much regretted at Oosterhout in the year 1747, and from whom Linnæus received singular and very important civilities; Kramer, since well known for an excellent treatise on the docimastic art; Van Royen, botanic professor at Leyden; Lieberkun of Berlin, famous for his skill in microscopical instruments and experiments. To these may be added also the names of Albinus and Gaubius, and of others, were it requisite to show that our author's talents had very early rendered him conspicuous, and gained him the regard of all those who cultivated and patronised any branch of medical science, and to which, doubtless, the singular notice with which Boerhaave honoured him do not a little contribute.

Early in the year 1738, after Linnæus had left Mr Clifford, and, as it should seem, when he resided with Van Royen, he had a long and dangerous fit of sickness; and upon his recovery went to Paris, where he was properly entertained by the Jusseus, at that time the first botanists in France. The opportunity this gave him of inspecting the Herbaria of Surian and Tournefort, and those of the above-named gentle-

men, afforded him great satisfaction. He had intended to have gone from thence into Germany, to visit Ludwig and the celebrated Haller, with whom he was in close correspondence; but he was not able to complete this part of his intended route, and was obliged to return without this gratification.

Our author did not fail to avail himself of every advantage that access to the several museums of this country afforded him, in every branch of natural history; and the number and importance of his publications, during his absence from his native country, sufficiently demonstrate that fund of knowledge which he must have imbibed before, and no less testify his extraordinary application. These were, *Systema Nature*, *Fundamenta Botanica*, *Bibliotheca Botanica*, and *Genera Plantarum*; the last of which is justly considered as the most valuable of all the works of this celebrated author. What immense application had been bestowed upon it, the reader may easily conceive, on being informed, that before the publication of the first edition the author had examined the characters of 8000 flowers. The last book of Linnæus's composition, published during his stay in Holland, was the *Classes Plantarum*, which is a copious illustration of the second part of the *Fundamenta*.

About the latter end of the year 1738, or the beginning of the next, our author settled as a physician at Stockholm; where he seems to have met with considerable opposition, and was oppressed with many difficulties; but all of these at length he overcame, and got into extensive practice; and soon after his settlement, married the lady before spoken of. By the interest of Count Tessin, who was afterwards his great patron, and even procured medals to be struck in honour of him, he obtained the rank of physician to the fleet, and a stipend from the citizens for giving lectures in botany. And what at this time especially was highly favourable to the advancement of his character and fame, by giving him an opportunity of displaying his abilities, was the establishment of the Royal Academy of Sciences at Stockholm; of which Linnæus was constituted the first president, and to which establishment the king granted several privileges, particularly that of free postage to all papers directed to the secretary. By the rules of the academy, the president held his place but three months. At the expiration of that term, Linnæus made his *Oratio de memorialibus in Insectis*, Oct. 3. 1739; in which he endeavours to excite an attention and inquiry into the knowledge of insects, by displaying the many singular phenomena that occur in contemplating the nature of those animals, and by pointing out, in a variety of instances, their usefulness to mankind in particular, and to the economy of nature in general.

During all this time, however, Linnæus appears to have had his eye upon the botanic and medical chair at Upsal, at this time occupied by Rudbeck, who was far advanced in life. We learn indeed that he was so intent on pursuing and perfecting his great designs in the advancement of his favourite study of nature, that he had determined, if he failed in procuring the professorship at Upsal, to accept the offer that had been made to him by Haller of filling the botanic chair at Gottingen. However, in course of time, he obtained his wish. In the year 1741, upon the resignation

Linnaeus.

signation of Roberg, he was constituted joint professor of physic and physician to the king with Rosen, who had been appointed in the preceding year on the death of Rudbeck. These two colleagues agreed to divide the medical departments between them; and their choice was confirmed by the university. Rosen took anatomy, physiology, pathology, and the therapeutic part; Linnaeus, natural history, botany, materia medica, the dietetic part, and the diagnosis morborum.

During the interval of his removal from Stockholm to Upsal in consequence of this appointment, our professor was deputed by the states of the kingdom to make a tour to the islands of Öland and Gothland in the Baltic, attended by six of the pupils, commissioned to make such inquiries as might tend to improve agriculture and arts in the kingdom, to which the Swedish nation had for some time paid a particular attention. The result of this journey was very successful, and proved fully satisfactory to the states, and was afterwards communicated to the public. On his return he entered upon the professorship, and pronounced before the university his oration *de Peregrinationum intra Patriam necessitate*, October 17. 1741; in which he forcibly displays the usefulness of such excursions, by pointing out to the students that vast field of objects which their country held out to their cultivation, whether in geography, physics, mineralogy, botany, zoology, or economics, and by showing the benefit that must accrue to themselves and their country as rewards to their diligence. That animated spirit which runs through the whole of this composition, renders it one of the most pleasing and instructive of all our author's productions.

Linnaeus was now fixed in the situation that was the best adapted to his character, his taste, and abilities; and which seems to have been the object of his ambition and centre of his hopes. Soon after his establishment, he laboured to get the academical garden, which had been founded in 1657, put on a better footing, and very soon effected it; procuring also a house to be built for the residence of the professor. The whole had been in ruin ever since the fire in 1702; and at the time Linnaeus was appointed professor of botany, the garden did not contain above fifty plants that were exotic. His correspondence with the first botanists in Europe soon supplied him with great variety. He received Indian plants from Jussieu of Paris, and from Van Royen of Leyden; European plants from Halker and Ludwig; American plants from the late Mr Collinson, Mr Cateby, and others; and variety of annuals from Dillenius: in short, how much the garden owed to his diligence and care in a few years, may be seen by the catalogue published under the title of *Hortus Upsalienfis, exhibens Plantas exoticas hortu Upsalienfis Academiae a seculo (Linnaeo) illatas ab anno 1742, in annum 1748, additis, differentiis synonymis, habitationibus, testimoniis, roriorumque descriptionibus, ingratiam studiosæ juventutis*; Holm. 1748, 8vo, pp. 306. tab. 3. By this catalogue it appears, that the professor had introduced 1100 species, exclusively of all the Swedish plants and of varieties; which latter, in ordinary gardens, amount not unfrequently to one-third of the whole number. The preface contains a curious history of the climate at Upsal, and the progress of the seasons throughout the whole year.

Linnaeus.

From the time that Linnaeus and Rosen were appointed professors at Upsal, it should seem that the credit of that university, as a school of physic, had been increasing: numbers of students resorted thither from Germany, attracted by the character of these two able men; and in Sweden itself many young men were invited to the study of physic by the excellent manner in which it was taught, who otherwise would have engaged in different pursuits.

Whilst Linnaeus was meditating one of his capital performances, which had long been expected and greatly wished for, he was interrupted by a tedious and painful fit of the gout, which left him in a very weak and dispirited state; and, according to the intelligence that his friends gave of him, nothing was thought to have contributed more to the restoration of his spirits than the seasonable acquisition, at this juncture, of a collection of rare and undescribed plants.

The fame which our author had now acquired by his *Système Naturel*, of which a sixth edition, much enlarged, had been published at Stockholm in 1748 in 8vo, pp. 232. with eight tables explanatory of the classes and orders (and which was also republished by Gronovius at Leyden, had brought, as it were, a conflux of every thing rare and valuable in every branch of nature, from all parts of the globe, into Sweden. The king and queen of Sweden had their separate collections of rarities; the former at Ulricksfahl; the latter, very rich in exotic insects and shells, procured at a great expence, at the palace of Drottningholm; both of which our author was employed in arranging and describing. Besides these, the museum of the royal academy of Upsal had been augmented by a considerable donation from the king, whilst hereditary prince, in 1746; by another from Count Gyllenborg the year before; by a third from M. Grill, an opulent citizen of Stockholm.

From this time we see the professor in a more elevated rank and situation in life. His reputation had already procured him honours from almost all the royal societies in Europe; and his own sovereign, truly sensible of his merit, and greatly esteeming his character and abilities, favoured him with a mark of his distinction and regard, by creating him a knight of the polar star. It was no longer *laudatur et alget*. His emoluments kept pace with his fame and honours: his practice in his profession became lucrative; and we find him soon after possessed of his country-house and gardens at Hammarby, about five miles from Upsal. He had moreover received one of the most flattering testimonies of the extent and magnitude of his fame that perhaps was ever shewn to any literary character, the state of the nation which conferred it, with all its circumstances, duly considered. This was an invitation to Madrid from the king of Spain, there to preside as a naturalist, with the offer of an annual pension for life of 2000 pitoles, letters of nobility, and the perfect free exercise of his own religion: But, after the most free and grateful acknowledgments of the singular honour done him, he returned for answer, 'that if he had any merits, they were due to his own country.'

In the year 1755, the Royal Academy of Sciences at Stockholm honoured our professor with one of the first premiums, agreeably to the will of Count Sparre;

whom

Linnaeus. who had decreed two gold medals, of ten ducats value each, to be annually given by the academy to the authors of such papers, in the preceding year's Stockholm Acts, as should be adjudged most useful in promoting agriculture particularly, and all branches of rural economy. This medal bore on one side the arms of the count, with this motto, *Superstes in scientiis amor Frederici Sparre*. Linnaeus obtained it in consequence of a paper *De Plantis quæ Alpium Suecicarum indigene, magno rei economiæ et medicæ emolumento fieri possunt*; and the ultimate intention was to recommend these plants, as adapted to culture in Lapland. This paper was inserted in the Stockholm Acts for 1754, Vol. XV. Linnaeus also obtained the *premium centum aureorum*, proposed by the Imperial academy of sciences at Peterburg, for the best paper written to establish or disprove, by new arguments, the doctrine of the sexes of plants. It was, if possible, an additional glory to Linnaeus to have merited this premium from the Peterburg academy; inasmuch as a professor of that society, a few years before, had with more than common zeal, although with a futility like that of the other antagonists of our author, endeavoured to overturn the whole Linnaean system of botany, by attempting to show that the doctrine of the sexes of plants had no foundation in nature, and was unsupported by facts and experiments.

It appears that Linnaeus, upon the whole, enjoyed a good constitution; but that he was sometimes severely afflicted with a *hemiparesis*, and was not exempted from the gout. About the close of 1776, he was seized with an apoplexy, which left him paralytic; and at the beginning of the year 1777, he suffered another stroke, which very much impaired his mental powers. But the disease supposed to have been the more immediate cause of his death, was an ulceration of the urinary bladder; of which, after a tedious indisposition, he died, January 11. 1778, in the 71st year of his age.—His principal other works, beside those already mentioned, are, *The Iter Oelandicum et Gothlandicum*, *Iter Scanicum*, *Flora Suecica*, *Fauna Suecica*, *Materia Medica*, *Philosophia Botanica*, *Genera Morborum*, different papers in the *Acta Upsalienfis*, and the *Amenitates Academicæ*. The last of this great man's treatises was the *Maniſſa Altera*, published in 1771; but before his death he had finished the greatest part of the *Maniſſa Tertia*, afterwards completed and published by his son.

To the lovers of science it will not appear strange, nor will it be unpleasant to hear, that uncommon respect was shewn to the memory of this great man. We are told, that "on his death a general mourning took place at Upsal, and that his funeral procession was attended by the whole university, as well professors as students, and the pall supported by sixteen doctors of physic, all of whom had been his pupils." The king of Sweden, after the death of Linnaeus, ordered a medal to be struck, of which one side exhibits Linnaeus's bust and name, and the other Cybele, in a dejected attitude, holding in her left hand a key, and surrounded with animals and growing plants; with this legend, *Deum lætus angit amisti*; and beneath, *Post obitum Upsalæ, die x. Jan. m.dcc.lxxxviii. Regre jubente*.—The same generous monarch not only honoured the Royal Academy of Sciences with his presence when Linnaeus's

Nº 183.

commemoration was held at Stockholm, but, as a still higher tribute, in his speech from the throne to the assembly of the states, he lamented Sweden's loss by his death. Nor was Linnaeus honoured only in his own country. The late worthy professor of botany at Edinburgh, Dr Hope, not only pronounced an eulogium in honour of him before his students at the opening of his lectures in the spring 1778, but also laid the foundation-stone of a monument (which he afterwards erected) to his memory, in the botanic garden there; which, while it perpetuates the name and merits of Linnaeus, will do honour to the founder, and, it may be hoped, prove the means of raising an emulation favourable to that science which this illustrious Swede so highly dignified and improved.

As to the private and personal character of this illustrious philosopher: His stature was diminutive and puny; his head large, and his hinder part very high; his look was ardent, piercing, and apt to daunt the beholder; his ear not sensible to music; his temper quick, but easily appeased.

Nature had, in an eminent manner, been liberal in the endowments of his mind. He seems to have been possessed of a lively imagination, corrected however by a strong judgment, and guided by the laws of system. Add to these, the most retentive memory, an unremitting industry, and the greatest perseverance in all his pursuits; as is evident from that continued vigour with which he prosecuted the design, that he appears to have formed so early in life, of totally reforming and fabricating anew the whole science of natural history; and this fabric he raised, and gave to it a degree of perfection unknown before; and had moreover the uncommon felicity of living to see his own structure rise above all others, notwithstanding every discouragement its author at first laboured under, and the opposition it afterwards met with. Neither has any writer more cautiously avoided that common error of building his own fame on the ruin of another man's. He every where acknowledged the several merits of each author's system; and no man appears to have been more sensible of the partial defects of his own. Those anomalies which had principally been the objects of criticism, he well knew every artificial arrangement must abound with; and having laid it down as a firm maxim, that every system must finally rest on its intrinsic merit, he willingly commits his own to the judgment of posterity. Perhaps there is no circumstance of Linnaeus's life which shows him in a more dignified light than his conduct towards his opponents. Disavowing controversy, and justly considering it as an unimportant and fruitless sacrifice of time, he never replied to any, numerous as they were at one season.

To all who feel the aid this extraordinary man has brought to natural science, his talents must appear in a very illustrious point of view; but more especially to those who, from similarity of taste, are qualified to see more distinctly the vast extent of his original design, the greatness of his labour, and the elaborate execution he has given to the whole. He had a happy command of the Latin tongue, which is alone the language of science; and no man ever applied it more successfully to his purposes, or gave to description such copiousness, united with that precision and conciseness which so eminently characterise his writings.

The

Linnaeus,
Linnet.

The ardour of Linnaeus's inclinations to the study of nature, from his earliest years, and that uncommon application which he bestowed upon it, gave him a most comprehensive view both of its pleasures and usefulness, at the same time that it opened to him a wide field hitherto but little cultivated, especially in his own country. Hence he was early led to regret, that the study of natural history, as a public institution, had not made its way into the universities; in many of which, logical disquisitions and metaphysical theories had too long prevailed, to the exclusion of more useful science. Availing himself therefore of the advantages which he derived from a large share of eloquence, and an animated style, he never failed to display, in a lively and convincing manner, the relation this study hath to the public good; to incite the great to countenance and protect it; to encourage and allure youth into its pursuits, by opening its manifold sources of pleasure to their view, and showing them how greatly this agreeable employment would add, in a variety of instances, both to their comfort and emolument. His extensive view of natural history, as connected with almost all the arts of life, did not allow him to confine these motives and incitements to those only who were designed for the practice of physic. He also laboured to inspire the great and opulent with a taste for this study; and wished particularly that such as were devoted to an ecclesiastical life should share a portion of natural science; not only as a means of sweetening their rural situation, confined, as many are, perpetually to a country residence, but as what would almost inevitably lead, in a variety of instances, to discoveries which only such situations could give rise to, and which the learned in great cities could have no opportunities to make. Not to add, that the mutual communication and enlargement of this kind of knowledge among people of equal rank in a country situation, must prove one of the strongest bonds of union and friendship, and contribute, in a much higher degree than the usual perishing amusements of the age, to the pleasures and advantage of society.

Linnaeus lived to enjoy the fruit of his own labour in an uncommon degree. Natural history raised itself in Sweden, under his culture, to a state of perfection unknown elsewhere; and was from thence disseminated through all Europe. His pupils dispersed themselves all over the globe; and, with their master's fame, extended both science and their own: More than this, he lived to see the sovereigns of Europe establish several public institutions in favour of this study; and even professorships established in divers universities for the same purpose, which do honour to their founders and patrons, and which have excited a curiosity for the science, and a sense of its worth, that cannot fail to further its progress, and in time raise it to that rank which it is intitled to hold among the pursuits of mankind.

LINNET, in ornithology. See FRINGILLA.—It is remarkable of this bird, that when it builds in hedges, and when in furze-bushes on heaths, in both which places the nests are very common, they are made of very different materials. When they build in hedges, they use the slender filaments of the roots of trees, and the down of feathers and thistles; but when they build on heaths, they use moss, principally for the outer part, finishing it within with such things as the place

Vol. X. Part I.

will afford. These birds will have young ones three or four times a-year, especially if they are taken away before they are able to leave the nests.

When linnets are to be taught to whistle tunes, or to imitate the notes of any other bird, they must be taken from the old one when they are not above four days old; for at this time they have no idea of the note of the old ones, and will be readily taught to modulate their voice like any thing that is most familiar to their ears, and within the compass of their throats. More care is required in feeding them when taken thus young, than when they are left in the nest till nearly fledged; but they will be reared very well upon a food half bread and half rape-seed boiled and bruised: this must be given them several times a-day. It must be made fresh every day, and given them sufficiently moist, but not in the extreme. If it be in the least sour, it gripes and kills them; and if too stiff, it is as mischievous by binding them up.—They must be hung up as soon as taken from the nest, under the bird whose note they are intended to learn; or, if they are to be taught to whistle tunes, it must be done by giving them lessons at the time of feeding; for they will profit more, while young, in a few days, than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard seeds. Some have attempted to learn them to speak in the manner of the parrot or other birds; and they will arrive at some sort of perfection in it, with great pains.

LINSEED, the seed of the plant linum.—Linseed steeped and bruised in water gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtue to it. See LINUM.

LINT. See FLAX, LINEN, and LINUM.

LINT, in surgery, is the scrapings of fine linen, used by surgeons in dressing wounds. It is made into various forms, which acquire different names according to the difference of their figures.—Lint made up in an oval or orbicular form is called a *pledgit*; if in a cylindrical form, or in shape of a date, or olive-stone, it is called a *dosfil*.

These different forms of lint are required for many purposes; as, 1. To stop blood in fresh wounds, by filling them up with dry lint before the application of a bandage: though, if scraped lint be not at hand, a piece of fine linen may be torn into small rags, and applied in the same manner. In very large hæmorrhages the lint or rags should be first dipped in some styptic liquor, as alcohol, or oil of turpentine; or sprinkled with some styptic powder. 2. To agglutinate or heal wounds; to which end lint is very serviceable, if spread with some digestive ointment, balsam, or vulnerary liquor. 3. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4. In keeping the lips of wounds at a proper distance, that they may not hastily unite before the bottom is well digested and healed. 5. They are highly necessary to preserve wounds from the injuries of the air.—Surgeons of former ages formed compresses of sponge, wool, feathers, or cotton; linen being scarce: but lint is far preferable to all these, and is at present universally used.

LINTERNUM, or LITERUM, (anc. geog.), a city of Campania, situated at the mouth of the Clanus, which is also called Liturnus, between Cumæ and Vul-

Linseed
Linnet.

Lintock
||
Linum.

Vulturum. It received a Roman colony at the same time with Puteoli and Vulturum; was improved and enlarged by Augustus; afterwards forfeited its right of colonyship, and became a prefecture. Hither Scipio Africanus the Elder retired from the mean envy of his ungrateful countrymen; and here he died, and was buried: though this last is uncertain, he having a monument both here and at Rome. No vestige of the place now remains.

LINTSTOCK, in military affairs, a wooden staff about three feet long, having a sharp point in one end and a sort of fork or crotch on the other; the latter of which serves to contain a lighted match, and by the former the lintstock is occasionally stuck in the ground, or in the deck of a ship during an engagement. It is very frequently used in small vessels, where there is commonly one fixed between every two guns, by which the match is always kept dry, and ready for firing.

LINTZ, a very handsome town of Germany, and capital of Upper Austria, with two fortified castles; the one upon a hill, the other below it. Here is a hall in which the states assemble, a bridge over the Danube, a manufacture of gunpowder, and several other articles. It was taken by the French in 1741, but the Austrians retook it in the following year. E. Long. 14. 33. N. Lat. 48. 16.

LINTZ, a town of Germany, in the circle of the Lower Rhine, and electorate of Cologne, subject to that elector. It is seated on the river Rhine, in E. Long. 7. 1. N. Lat. 50. 31.

LINUM, FLAX; a genus of the pentagynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 14th order, *Grinales*. The calyx is pentaphyllous; the petals are five, the capsule is quinquevalved and decemlocular; and the seeds are solitary.

Species. 1. The *utilissimum*, or common annual flax, hath a taper fibrous root; upright, slender, unbranched stalks, two feet and a half high; garnished with narrow, spear-shaped, alternate grey-coloured leaves; and the stalks divided into footstalks at top, terminated by small blue crenated flowers in June and July; succeeded by large round capsules of ten cells, containing each one seed. 2. The perenne, or perennial Siberian flax, hath a fibrous perennial root, sending up several upright, strong, annual stalks, branching four or five feet high; garnished with small narrow, spear-shaped, alternate leaves of a dark green colour; and terminated by umbellate clusters of large blue flowers in June, succeeded by seeds in autumn. 3. The catharticum, or purging flax, with leaves opposite and lanceolate; the stem bifurcated, and the corollæ acute. This is a very small plant, not above four or five inches high; found wild upon chalky hills and in dry pleasure-grounds. There are 18 other species.

Culture. The first species is cultivated in the fields according to the directions given under the article **FLAX**. The second sort is raised from seed in a bed or border of common garden-earth, in shallow drills six inches asunder; and when the plants are two or three inches high, thin them to the same distance; and in autumn plant them out where they are wanted.

Uses. The first species may justly be looked upon as one of the most valuable of the whole vegetable kingdom; as from the bark of its stalks is manufac-

tured the lint or flax for making all sorts of linen-cloth; from the rags of the linen is-made paper; and from the seeds is expressed the lintseed oil so useful in painting and other trades. The seeds themselves are esteemed an excellent emollient and anodyne: they are used externally in cataplasms, to alluage the pain of inflamed tumors; internally, a slight infusion of lintseed, by way of tea, is recommended in coughs as an excellent pectoral, and of great service in pleurisies, nephritic complaints, and suppressions of urine. The virtue of the third species is expressed in its title: an infusion in water or whey of a handful of the fresh leaves, or a dram of them in substance when dried, are said to purge without inconvenience.

LINUS, in classical history, a native of Colchis, cotemporary with Orpheus, and one of the most ancient poets and musicians of Greece. It is impossible, at this distance of time, to discover whether Linus was the disciple of Orpheus, or Orpheus of Linus. The majority, however, seem to decide this question in favour of Linus. According to archbishop Usher, he flourished about 1280 B. C. and he is mentioned by Eusebius among the poets who wrote before the time of Moses. Diodorus Siculus tells us, from Dionysius of Mitylene the historian, who was cotemporary with Cicero, that Linus was the first among the Greeks who invented verses and music, as Cadmus first taught them the use of letters. The same writer likewise attributes to him an account of the exploits of the first Bacchus, and a treatise upon Greek mythology, written in Pelasgian characters, which were also those used by Orpheus, and by Pronapides the preceptor of Homer. Diodorus says that he added the string *lichanos* to the Mercurian lyre; and ascribes to him the invention of rhyme and melody; which Suidas, who regards him as the most ancient of lyric poets, confirms. Mr Marpurge tells us, that Linus invented cat-gut strings for the use of the lyre, which, before his time, was only strung with thongs of leather, or with different threads of flax strung together. He is said by many writers to have had several disciples of great renown; among whom were Hercules, Thamyris, and, according to some, Orpheus—Hercules, says Diodorus, in learning from Linus to play upon the lyre, being extremely dull and obstinate, provoked his master to strike him; which so enraged the young hero, that, instantly seizing the lyre of the musician, he beat out his brains with his own instrument.

LION, in zoology. See **FELIS**.

LIONCELLES, in heraldry, a term used for several lions borne in the same coat of arms.

LIOTARD, called the *Turk*, an eminent painter, was born at Geneva in 1702, and by his father was designed for a merchant; but, by the persuasion of his friends, who observed the genius of the young man, he was permitted to give himself up to the art of painting. He went to Paris in 1725, and in 1738 accompanied the marquis de Puifieux to Rome, who was going ambassador to Naples. At Rome he was taken notice of by the earls of Sandwich and Belborough, then lord Duncannon, who engaged Liotard to go with them on a voyage to Constantinople. There he became acquainted with the late Lord Edgecumbe, and Sir Everard Fawkener, our ambassador, who persuaded him to come to England, where he staid two years. In his journey to the Levant he had adopted the eastern habit.

habit, and wore it here with a very long beard. It contributed much to the portraits of himself, and some thought to draw customers; but he was really a painter of uncommon merit. After his return to the continent, he married a young wife, and sacrificed his beard to Hymen. He came again to England in 1772, and brought a collection of pictures of different masters, which he sold by auction, and some pieces of glass painted by himself, with surprising effect of light and shade, but a mere curiosity, as it was necessary to darken the room before they could be seen to advantage; he asked, too, as usual, extravagant prices to them. He staid here about two years, as in his former journey. He has engraved some Turkish portraits, one of the empress queen and the eldest arch-duchess in Turkish habits, and the heads of the emperor and empress. He painted admirably well in miniature; and finely in enamel, though he seldom practised it. But he is best known by his works in crayons. His likenesses were as exact as possible, and too like to please those who sat to him; thus he had great business the first year, and very little the second. Devoid of imagination, and one would think of memory, he could render nothing but what he saw before his eyes. Freckles, marks of the small-pox, every thing found its place; not so much from fidelity, as because he could not conceive the absence of any thing that appeared to him. Truth prevailed in all his works, grace in very few or none. Nor was there any ease in his out-line; but the stiffness of a bust in all his portraits. *Walpole.*

LIP, in anatomy. See there, n^o 102.

Hare-Lip, a disorder in which the upper lip is in a manner slit or divided, so as to resemble the upper lip of a hare, whence the name. See *SURGERY*.

LIPARA (anc. geog.), the principal of the islands called *Eolias*, situated between Sicily and Italy, with a cognominal town, so powerful as to have a fleet, and the other islands in subjection to it. According to Diodorus Siculus, it was famous for excellent harbours and medicinal waters. He informs us also, that it suddenly emerged from the sea about the time of Hannibal's death. The name is Punic, according to Bochart: and given it, because, being a volcano, it shone in the night. It is now called *Lipari*, and gives name to nine others in its neighbourhood; viz. Stromboli, Pare, Rotto, Panaria, Saline, Volcano, Fenicufa, Alicori, and Ustica. These are called, in general, the *Lipari Islands*. Some of these are active volcanoes at present, though Lipari is not. It is about 15 miles in circumference; and abounds in corn, figs, and grapes; bitumen, sulphur, alum, and mineral waters.

LIPARI, an ancient and very strong town, and capital of an island of the same name in the Mediterranean, with a bishop's see. It was ruined by Barbarossa in 1544, who carried away all the inhabitants into slavery, and demolished the place; but it was rebuilt by Charles V. E. Long. 15. 30. N. Lat. 38. 35.

Lipari, properly, is the general name of a cluster of islands. These, according to Mr Houel, are principally ten in number, the rest being only uninhabitable rocks of narrow extent. The largest and the most populous of them, that above-mentioned, communicates its name to

the rest. *Volcano* is a desert but habitable island, lying south from the large island of Lipari. *Salines*, which lies west-north-west from the same island; *Felicudi*, nearly in the same direction, but twenty miles farther distant; and *Alicudi*, ten miles south-west of *Felicudi*; are inhabited. *Pannari* is east of Lipari, the famous *Stromboli* north-east, and both of them are inhabited. The rest are in a desert state; such as *Basiluzzo*, which was formerly inhabited; *Atalio*, which might be inhabited; and *L'Exambianca*, on which some remains of ancient dwellings are still to be found. *L'Escanera* is nothing but a bare rock.

The *Femicoli*, a word signifying ants, are a chain of small black cliffs which run to the north-east of Lipari, till within a little way of Exambianca and Escanera, rising more or less above the water, according as the sea is more or less agitated.

Ancient authors are not agreed with respect to the number of the Lipari islands. Few of those by whom they are mentioned appear to have seen them: and in places such as these, where subterraneous fires burst open the earth and raise the ocean from its bed, terrible changes must sometimes take place. *Volcanella* and *Volcano* were once separated by a straight sea as to form two islands. The lava and ashes have filled up the intervening strait; and they are now united into one island, and have by this change become much more habitable.

The castle of Lipari stands on a rock on the east quarter of the island. The way to it from the city leads up a gentle declivity. There are several roads to it. This castle makes a part of the city; and on the summit of the rock is the citadel, in which the governor and the garrison resides. The cathedral stands in the same situation. Here the ancients, in conformity to their usual practice, had built the temple of a tutelary god. This citadel commands the whole city; and it is accessible only at one place. Were an hostile force to make a descent on the island, the inhabitants might retreat thither, and be secure against all but the attacks of famine.

The ancient inhabitants had also fortified this place. Considerable portions of the ancient walls are still standing in different places, particularly towards the south: their structure is Grecian; and the stones are exceedingly large, and very well cut. The layers are three feet high, which shows them to have been raised in some very remote period. These remains are surrounded with modern buildings. The remains of walls, which are still to be seen here, have belonged not only to temples, but to all the different sorts of buildings which the ancients used to erect. The vaults, which are in a better state of preservation than any of the other parts of these monuments, are now converted to the purposes of a prison.

In the city of Lipari there are convents of monks of two different orders; but there are no convents for women, that is to say, no cloisters in which women are confined; those, however, whose heads and hearts move them to embrace a state of pious celibacy, are at liberty to engage in a monastic life, with the concurrence of their confessors. They put on the sacred habit, and vow perpetual virginity, but continue to live with their father and mother, and mix in society like other women. The vow and the habit even enlarge

Lipari.

their liberty. This custom will, no doubt, M. Houel observes, appear very strange to a Frenchwoman; but this was the way in which the virgins of the primitive church lived. The idea of shutting them up together did not occur till the fifth century. The life of these religious ladies is less gloomy than that which those under the same vows lead in other countries. They wear cloaths of particular colours, according as they belong to this or that order. Their dress gives them a right to frequent the churches at any hours; and the voice of censure, which takes particular pleasure in directing her attacks against pious ladies, goes so far as to assert, that some young women assume the habit with no other views but that they may enjoy greater freedom.

In this island oxen of a remarkably beautiful species are employed in ploughing the ground. The ancient plough is still in use here. The mode of agriculture practised here is very expeditious. One man traces a furrow, and another follows to sow in it grain and pulse. The ploughman, in cutting the next furrow, covers up that in which the seed has been sown: and thus the field is both ploughed and sown at once. Nature seems to be here uncommonly vigorous and fertile. Vegetation is here more luxuriant, and animals gayer and more healthful, than almost any where else.

Near the city of Lipari, the traveller enters deep narrow roads, of a very singular appearance. The whole island is nothing but an assemblage of mountains, all of them consisting of ashes or lava discharged from the depths of the volcano by which it was at first produced. The particles of this puzzolana, or ashes, are not very hard; the action of the rain-water has accordingly cut out trenches among the mountains; and these trenches being perhaps less uneven than the rest of the surface, have of consequence been used as roads by the inhabitants, and have been rendered much deeper by being worn for so many ages by the feet of men and other animals. These roads are more than five or six fathoms deep, and not more than seven or eight feet wide. They are very crooked, and have echoes in several places. You would think that you were walking through narrow streets without doors or windows. Their depth and windings shelter the traveller from the sun while he is passing through them; and he finds them deliciously cool.

The first volcanic eruption in the Lipari islands, mentioned in history, is that of which Callias takes notice of in his history of the wars in Sicily. Callias was contemporary with Agathocles. That eruption continued without interval for several days and nights; and threw out great stones, which fell at more than a mile's distance. The sea boiled all around the island. The works of Callias are lost, and we know not whether he descended to a detail of particulars concerning the ravages produced by this eruption. Under the consulship of Æmilius Lepidus and L. Aurelius Orestes, 126 years before the Christian era, these islands were affected with a dreadful earthquake. The burning of Ætna was the first cause of that. Around Lipari and the adjacent islands, the air was all on fire. Vegetation was withered; animals died; and fusible bodies, such as wax and resin, became liquid. If the inhabitants of Lipari, from whom our author received these facts, and the writers who have handed down an ac-

count of them, have not exaggerated the truth, we must believe that the sea then boiled around the island; the earth became so hot as to burn the cables by which vessels were fixed to the shore, and consumed the planks, the oars, and even the small boats.

Pliny, the naturalist*, speaks of another similar event which happened 30 or 40 years afterwards, in the time of the war of the allied states of Italy against Rome. One of the Eolian islands, says he, was all on fire as well as the sea; and that prodigy continued to appear, till the senate appealed, by a deputation, the wrath of the gods. From the time of that war, which happened 86 years before the birth of our Saviour; till the year 144 of our era, we have no account of any eruption of these volcanoes: and from that period again, till the year 1444, we hear of no explosion from them, that is, for the space of 1300 years. But, at that time, both Sicily and the Eolian isles were agitated by dreadful shocks of earthquake: the volcano of these isles poured forth streams of lava with an awful violence, and emitted a volume of flame and smoke which rose to an amazing height. After that it discharged enormous stones which fell at the distance of more than six miles.

A century later, in the year 1550, the fury of this volcano was again renewed. The ashes and stones discharged from the crater filled up the strait between Volcano and Volcanello.

About two centuries after that, in the year 1739, there was a sixth eruption. The burblings of the volcanic fire were attended with a noise so dreadful, that it was heard as far as Melazzo in Sicily.

Father Leandro Alberti says, that on one of those dreadful occasions, the women of Lipari, after employing in vain all the saints, vowed to drink no more wine if the volcano should spare them. Their giving up this small gratification was doubtless of great service; yet the eruptions still continue, and have even become more frequent since that time. Only 36 years intervened between this eruption and that which happened in the year 1775. The whole island was then shaken; subterraneous thunder was heard; and considerable streams of flame, with smoke, stones, and vitreous lava, issued from the crater. Lipari was covered over with ashes; and part of itself was conveyed by the winds all the way into Sicily. Five years after, however, in the month of April 1780, there issued a new explosion from Volcano; the smoke was thick, the shocks constant, and the subterraneous noise very frequent. So great was the consternation among the inhabitants of Lipari on this occasion, that the commander Deodati Dolomicu, who visited these islands not long after that event, informs us, that the inhabitants in general, but especially the women, devoted themselves as slaves to the service of the blessed virgin; and wore on their arms, as tokens of their servitude, small iron chains, which they still continue to wear.

This act of piety, however, was not so efficacious as the deputation of the senate had been. For after that deputation, more than 200 years passed before the Eolian isles were afflicted by any other eruption, at least by any considerable one: Whereas, in three years after the ladies devoted themselves in so submissive a manner to the service of the virgin, the isles of Li-

Lipari.

* Lib. ii. cap. 106.

pari were agitated anew by that fatal earthquake which ravaged Calabria, and part of Sicily, on the 5th of February 1783.

The dry baths of St Calogero, in the island of Lipari, are fiores, where sulphureous exhalations, known to be of a salutary nature, ascend out of the earth by holes or spiracles. A range of apartments are built around the place where the exhalations arise. The heat is communicated through those apartments in such a way, that when entering at one end, you advance towards the other, the heat still increases upon you till you gain the middle apartment, and again diminishes in the same manner as you proceed from the middle to the other end of the range of chambers. In consequence of this disposition of these apartments, the sick person can make choice of that temperature which best suits the nature of his disease. There are a few miserable huts and a small chapel for the accommodation of the people who repair to these baths. The people of the place are ready to attend them. Physicians likewise follow their patients thither, when the disease is of such a nature as to render their attendance requisite, and the patient rich enough to afford them handsome fees: but there is no physician settled in the place. Besides these dry baths, there are baths of hot water distinguished by the name of *St Calogero's baths*. There are around them buildings sufficient to lodge a considerable number of sick people with their necessary attendants. At present, however, those buildings are but in a bad condition.

The baths consist of two halls; one square, the other round. The former is antique; it has been built by the Romans; it is arched with a cupola, and 12 feet in diameter; it has been repaired: The other is likewise arched with a cupola both within and without. The water comes very hot into the first. It gushes up from among pieces of lava, which compose a part of the mountain at the foot of which these baths are built. Those stones remain in their natural state. All that has been done is the raising of a square building inclosing them. Within that building the sick persons either sit down on the stones, or immerse themselves in the intervening cavities which are filled with water. They continue there for a certain time, and approach nearer to, or remain at a farther distance from, the spring, according as their physician directs. The place serves also as a stove. The hot vapours arising from the water communicate to the surrounding atmosphere a considerable degree of heat. It is indeed not inferior to that of the hot baths of Termini, which owe their heat to a similar cause. In these baths, therefore, a person can have the benefit either of bathing in the hot water, or of exposing himself to the vapour, the heat of which is more moderate. The bath before mentioned, under the appellation of *dry bath*, is also a stove; but the hot vapour with which it is filled issues directly from the volcano. The place of the bath is, however, at such a distance from the volcanic focus, that the heat is not at all intolerable.

The mountain at the foot of which these baths are situated is round, and terminates at the summit in a rock of petrified ashes, which are very hard and of a very fine grain. This petrification consists of pretty regular strata, and appears to have been greatly prior

in its origin to the adjacent rocks; which consist likewise of ashes, but ashes that have been deposited at a much later period. From this rock there proceeds likewise a stream of hot water, by which some mills in the neighbourhood are moved.

It cannot but appear surprising, that nature has placed nearly on the summit of a volcanic mountain springs which supply so considerable a quantity of water. To account for such a phenomenon would be well worthy of some ingenious naturalist. Nor are these hot springs all; proceeding around the same hill, at about a mile's distance, we find a spring of cold water, which originates from the summit of the same rock; that on the north-west produces three hot springs. The cold water is very pleasant to drink, and much used both by men and cattle.

Among these mountains there are many enormous loose masses of lava, the appearance of which, M. Houel informs us, naturally leads the observer to take notice, that the lava of the volcano of Lipari is of a much greater diversity of colours, and those richer and more lively, than the lava of Vesuvius and Etna: The lava of Lipari is in some places, for several miles, of a beautiful red colour. It contains likewise in great abundance small black crystallised scoriae, as well as the small white grains which are commonly found in lava.

Among the eminences which overlook the city of Lipari, there are some rocks of a species which is very rare in Europe. Those are large masses of vitrified matter, which rise six or eight feet above the surface of the ground, and appear to extend to a great depth under it. They exist, through that range of mountains, in enormous masses, mixed with lavas of every different colour, and always standing detached and insulated. Were they cut and followed under ground, they would probably be found to exist in immense quarries in the bowels of the earth. The glass of which they consist might be employed with great advantage in manufactures. It is ready made, and might be easily purified. It is green, compact, and transparent.

The cultivation of the ground is the chief employment of the inhabitants of Lipari. The possession of a few acres of land here gives a man great importance. Parents, when they settle their children, rather give them money than any part of their lands.

More than two-thirds of the island is planted with vines: three-fourths of the grapes which these produce are dried, and sent mostly to London under the name of *Passola*. There are different sorts of passola: one of these, called the *black passolina*, is prepared from a particular kind of grape, of which the berries are uncommonly small; and sold to Marseilles, Holland, and Trieste. The vines are in small arbours, which rise only to the height of two feet and an half above the ground. Under those arbours there grow beans, gourds, and other leguminous vegetables. In so hot a climate, the shade of the vines does not injure but protect the vegetables growing under it: they would otherwise be withered by the heat of the sun.

The method of preparing passola and passolina is curious enough: They first make a lixivium of common ashes; after boiling this, they pass it through a cloth or a sieve; they then put it again on the fire; and

when

Lipari
||
Lippi.

when it is observed to boil hard, suddenly immerse the grapes, but instantly bring them out again, and expose them to the sun to dry on broad frames of cane. When sufficiently dry, the raisins are put into casks and barrels to be sold and exported. The number of casks of different sorts of raisins annually exported from Lipari are estimated at 10,000.

This island likewise produces figs. There is some white malmsey and a little red wine exported from it.

About 60 or 80 years since, sulphur was one of the articles with which the inhabitants of this island supplied foreign merchants. But that trade has been given up; from an idea which the Liparese entertain, that sulphur infects the air so as to injure the fertility of the vines. The same prejudice prevails in Sicily; but it seems to be ill-founded.

There are courts of justice in Lipari, of the same powers and character with those in the cities of Sicily. Causes of more than ordinary importance are carried to Palermo.

The island is entirely free from every kind of imposition. The king receives nothing from it; because Count Roger anciently bestowed on its bishop all his rights of royalty over Lipari. The bishop there received annually from the inhabitants a tenth part of the products of their lands. They afterwards, to prevent fraud, estimated the value of that tithe for one year; and on the condition of their paying in future a sum of money equal to what that year's tithe was valued at, he not only gave up his right to the tithe, but also ceded to them a considerable extent of land which belonged to him.

In the archiepiscopal palace, and in the palace of the Baron de Monizio, there are some noble pieces of painting by Sicilian painters:—A St Peter, a St Rosalia, his disciples disputing with the Jewish doctors, the adulterous woman, the incredulity of St Thomas.

LIPOTHYMIA, FAINTING, may arise from several causes; as too violent exercise, suppression of the menses or other accustomed evacuations, &c. See (the *Index* subjoined to) MEDICINE.

LIPPA, a town of Hungary, with a castle. It was taken by the Turks in 1552; by the Imperialists in 1688; and by the Turks again in 1691; who abandoned it in 1695, after having demolished the fortifications. It is seated on a mountain, in E. Long. 21. 55. N. Lat. 36. 5.

LIPPE, the capital of a country of the same name in Germany, and the circle of Westphalia. It is seated on a river of the same name, and was formerly the residence of the principal branch of the house of Lippe. It is now in the possession of the king of Prussia, and carries on a good trade in preparing timber for building vessels on the Rhine, with which it has a communication by the river Lippe. The country round it is unwholesome and marshy. E. Long. 8. 12. N. Lat. 51. 43.

LIPPI (Lorenzo), a painter of history and portraits, was born in 1606, and learned the principles of painting from Matteo Roselli. He had an exquisite genius for music and poetry, as well as for painting; and in the latter, his proficiency was so great, that some of his compositions in the historical style were taken for those of Roselli. However, growing at last dissatisfied with the manner of that master, he chose the manner of Santi di Titi, who was excellent both in design and

invention, and appeared to have more of simple nature and truth in his compositions than any other artist of that time. At Florence Lippi painted many grand designs for the chapels and convents, by which he enlarged his reputation; and at the court of Inspruck, he painted a great number of portraits of the first nobility, which were deservedly admired. Yet, altho' he was fond of imitating simple nature without any embellishments from invention, his works are held in the highest esteem for the graceful airs of the heads, for the correctness of his outline, and for the elegant disposition of the figures. He died in 1664.

LIPSIUS (Justus), a learned critic, was born at Ilich, a small village near Brussels, in 1547. After having distinguished himself in polite literature, he became secretary to cardinal de Granvella at Rome, where the best libraries were open to him; and he spent much labour in collating the MSS. of ancient authors. He lived 13 years at Leyden; during which he composed and published what he esteems his best works; but settled at Louvain, where he taught polite literature with great reputation. He was remarkable for unsteadiness in religion, fluctuating often between the Protestants and Papists; but he became finally a bigotted catholic. He died at Louvain in 1606; and his works are collected in six volumes folio.

LIQUEFACTION, an operation by which a solid body is reduced into a liquid; or the action of fire or heat on fat and other fusible bodies, which puts their parts into a mutual intestine motion.—The liquefaction of wax, &c. is performed by a moderate heat; that of sal tartari, by the mere moisture of the air. All salts liquefy; sand, mixed with alkalies, becomes liquefied by a reverberatory fire, in the making of glass. In speaking of metals, instead of liquefaction, we ordinarily use the word *fusion*.

LIQUID, a body which has the property of fluidity; and, besides that, a peculiar quality of wetting other bodies immersed in it, arising from some configuration of its particles, which disposes them to adhere to the surfaces of bodies contiguous to them. See FLUID.

LIQUID, among grammarians, is a name applied to certain consonants opposed to mutes. Thus l, m, n, and r, are liquids.

LIQUIDAMBAR, SWEET-GUM-TREE, in botany: A genus of the polyandria order, belonging to the monœcia class of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is common, and triphyllous; there is no corolla, but numerous filaments; the female calyces are collected into a spherical form, and tetraphyllous; there is no corolla, but seven styles; and many bivalved and monospermous capsules collected into a sphere. There are only two species, both deciduous, viz. 1. The styraciflua, or the Virginia or maple-leaved liquidambar; a native of the rich moist parts of Virginia and Mexico. It will shoot in a regular manner to thirty or forty feet high, having its young twigs covered with a smooth, light-brown bark, while those of the older are of a darker colour. The leaves are of a lucid green, and grow irregularly on the young branches, on long footstalks: They resemble those of the common maple in figure; the lobes are all serrated; and from the base of the leaf a strong mid-

Liquor
||
Liquidambar.

Liquidambar. rib runs to the extremity of each lobe that belongs to it. The flowers are of a kind of saffron colour: They are produced at the ends of the branches the beginning of April, and sometimes sooner; and are succeeded by large round brown fruit, which looks singular, but is thought by many to be no ornament to the tree. 2. The peregrinum, Canada liquidambar, or spleenwort-leaved gale, is a native of Canada and Pennsylvania. The young branches of this species are slender, tough, and hardy. The leaves are oblong, of a deep green colour, hairy underneath, and have indentures on their edges alternately very deep. The flowers come out from the sides of the branches, like the former; and they are succeeded by small roundish fruit, which seldom ripens in England.

Propagation. This may be performed either by seeds or layers; but the first method is the best. 1. We receive the seeds from America in the spring. Against their arrival, a fine bed, in a warm well sheltered place, should be prepared. If the soil is not naturally good, and inclined to be sandy, it should be wholly taken out near a foot deep, and the vacancy filled up with earth taken up a year before from a fresh pasture with the sward, and all well rotted and mixed by being often turned, and afterwards mixed with a sixth part of drift or sea-sand. A dry day being made choice of, early in March, let the seeds be sown, and the finet of this compost riddled over them a quarter of an inch deep. When the hot weather in the spring comes on, the beds should be shaded, and waterings given often, but in very small quantities, only affording them a gentle, nay, a very small sprinkling, at a time. Millar says, the seeds of these plants never come up under two years. But, continues Hanbury, with this easy management, I hardly ever knew it longer than the end of May before the young plants made their appearance. The plants being come up, shading should still be afforded them in the parching summer, and a watering every other night; and this will promote their growth, and cause them to become stronger plants by the autumn. In the autumn, the beds should be hooped to be covered with mats in the severe frosts. These mats, however, should always be taken off in open weather; and this is all the management they will require during the first winter. The succeeding summer they will require no other trouble than weeding; though, if it should prove a dry one, they will find benefit from a little water now-and-then. By the autumn they will be grown strong enough to resist the cold of the following winter, without demanding the trouble of matting, if the situation is well sheltered; if not, it will be proper to have the hoops prepared, and the mats ready, against the black northern frosts, which would endanger at least their losing their tops. After this, nothing except weeding will be wanted; and in the spring following, that is, three years from their first appearance, they should be taken up (for they should not be removed before, unless some of the strongest plants be drawn out of the bed), and planted in the nursery a foot asunder, and two feet distant in the rows. Hoeing the weeds in the rows in the summer, and digging them in the winter, is all the trouble they will afterwards occasion until they are finally planted out. 2. These plants are easily increased by layers. The operation must be performed in the autumn, on the young summer's shoots; and the best way is by slit-

ting them at a joint, as is practised for carnations. In a strong dry soil, they will be often two years or more before they strike root; though, in a fine light soil, they will be found to take freely enough. By this method good plants may be obtained; though it is not so eligible as the other, if we have the convenience of procuring the seeds.

Properties. The leaves emit their odoriferous particles in such plenty as to perfume the circumambient air; nay, the whole tree exudes such a fragrant transparent resin, as to have given occasion to its being taken for the sweet storax †. These trees, therefore, are very proper to be planted singly in large opens, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume, but is at present a stranger in the shops.

LIQUOR, a name for any fluid substance of the aqueous or spirituous kind.

The principal beverage amongst the Jews, as well as the Greeks and Romans, in their early state, was water, milk, and the juices of various plants infused therein. For a long time, under the commonwealth of Rome, wine was so scarce, that in their sacrifices to the gods the libations were made with milk only. Wine did not become common there till A.U.C. 600, when vines began to be planted.

Liquor of Flint. See CHEMISTRY, n° 1069.

Smoking Liquor of Lilavius. See CHEMISTRY, n° 810.

Mineral Anodyne Liquor of Hoffman. This is a composition of highly rectified spirit of wine, vitriolic ether, and a little of the dulcified oil of vitriol. It is made by mixing an ounce of the spirit of wine, which rises first in the distillation of ether, with as much of the liquor which is to be distilled, and afterwards by dissolving in the mixture which rises next, and which contains the ether, 12 drops of the oil which rises after the ether is passed. This has the same virtues with the ether, and is now generally disused, the pure ether being substituted in its place.

LIQUORICE. See GLYCRRHIZA.

LIRIODENDRON, the TULIP-TREE, in botany: A genus of the polyginia order, belonging to the polyandria class of plants; and in the natural method ranking under the 52d order, *Cochonate*. The calyx is triphyllous; there are nine petals; and the seeds imbricated in such a manner as to form a cone.—There is but one species, viz. the *lulipifera*, a deciduous tree, native of most part of America. It rises with a large upright trunk, branching 40 or 50 feet high. The trunk, which often attains to a circumference of 30 feet, is covered with a grey bark. The branches, which are not very numerous, of the two-years-old wood, are smooth and brown; while the bark of the summer's shoots is smoother and shining, and of a bluish colour. They are very pithy. Their young wood is green, and when broken emits a strong scent. The leaves grow irregularly on the branches, on long footstalks. They are of a particular structure, being composed of three lobes, the middlemost of which is shortened in such a manner that it appears as if it had been cut off and hollowed at the middle: The two others are rounded off. They are about four or five inches long, and as many broad. They are of two colours; their upper surface is smooth, and of a stronger green than the lower. They fall off pretty early in au-

Liedendron,
Lis.

turn; and the buds for the next year's shoots soon after begin to swell and become dilated, inasmuch that, by the end of December, those at the ends of the branches will become near an inch long and half an inch broad. The outward laminae of these leaf-buds are of an oval figure, have several longitudinal veins, and are of a bluish colour. The flowers are produced with us in July, at the ends of the branches: They somewhat resemble the tulip, which occasions its being called the Tulip-tree. The number of petals of which each is composed, like those of the tulip, is six; and these are spotted with green, red, white, and yellow, thereby making a beautiful mixture. The flowers are succeeded by large cones, which never ripen in England.

Propagation. This is very easy, if the seeds are good; for by these, which we receive from abroad, they are to be propagated. No particular compost need be sought for; neither is the trouble of pots, boxes, hot-beds, &c. required: They will grow exceedingly well in beds of common garden-mould, and the plants will be hardier and better than those raised with more tenderness and care. Therefore, as soon as you receive the seeds, which is generally in February, and a few dry days have happened, so that the mould will work freely, sow the seeds, covering them three quarters of an inch deep; and in doing of this, observe to lay them lengthwise, otherwise, by being very long, one part, perhaps that of the embryo plant, may be out of the ground soon, and the seed be lost. This being done, let the beds be hooped; and as soon as the hot weather and drying winds come on in the spring, let them be covered from ten o'clock in the morning till sun-set. If little rain happens, they must be duly watered every other day; and by the end of May the plants will come up. Shade and watering in the hottest summer must be afforded them, and they will afterwards give very little trouble. The next winter they will want no other care than, at the approach of it, sticking some furze-bushes round the bed, to break the keen edge of the black frosts; for it is found that the seedlings of this sort are very hardy, and seldom suffer by any weather. After they have been two years in the seed-bed, they should be taken up and planted in the nursery, a foot asunder, and two feet distant in the rows. After this, the usual nursery care of hoeing the weeds, and digging between the rows in the winter, will suffice till they are taken up for planting out.

Uses. The tulip-tree, in those parts of America where it grows common, affords excellent timber for many uses: particularly, the trunk is frequently hollowed, and made into a canoe sufficient to carry many people; and for this purpose no tree is thought more proper by the inhabitants of those parts. With us, it may be stationed among trees of forty-foot growth.

LIS or LYS (John Vander), painter of history, landscapes, and conversations, was born at Oldenburgh in 1570, but went to Harlem to place himself as a disciple under Henry Goltzius; and as he was endowed with great natural talents, he soon distinguished himself in that school, and imitated the manner of his master with great success. He adhered to the same style till he went to Italy; where, having visited Venice and Rome, he studied the works of Titian, Tintoretto, Paolo Veronese, and Domenico Fetti, so effectually, that he improved his taste and judgment, and altered

his manner entirely. He soon received marks of public approbation; and his compositions became universally admired for their good expression, for their lively and natural colouring, and the sweetness and delicacy of his pencil: although it must be acknowledged, that he could never totally divest himself of the ideas and taste peculiar to the Flemings. His subjects usually were histories taken from the sacred writings, or the representation of rural sports, marriages, balls, and villagers dancing, dressed in Venetian habits; all which subjects he painted in a small as well as a large size, with a number of figures, well designed, and touched with a great deal of delicacy. He was likewise accounted to paint naked figures admirably, with natural and elegant attitudes, and a very agreeable turn of the limbs. A capital picture of this master is, Adam and Eve lamenting the death of Abel; which is extremely admired, not only for the expression, but also for the beauty of the landscape: and in the church of St Nicholas at Venice is another of his paintings, representing St Jerom in the desert, with a pen in his hand, and his head turned to look at an angel, who is supposed to be sounding the last trumpet. The colouring [of this picture is rather too red; but it is designed in a fine style, and charmingly pencilled. The paintings of this master are very rarely to be purchased. He died in 1629.

LIS (John Vander) of Breda, historical painter, was born at Breda about the year 1661, and became a disciple of Cornelius Polemburg, whose manner he imitated with extraordinary exactness, in the tints of his colouring, his neatness of pencilling, and the choice of his subjects. There are some paintings of this master's hand, which, tho' they appear to have somewhat less freedom and lightness of touch, are nearly equal to those of Polemburg, and are frequently taken to be his. At Rotterdam, in the possession of Mr Bisschop, there is a delicate painting representing Diana in the Bath, attended by her nymphs; and his most capital performance, in England, is said to be in the possession of the Viscount Middleton. The portrait of Vander Lis, painted by himself, is in the possession of Horace Walpole, Esq; which is described by that ingenious gentleman, as being worked up equal to the smoothness of enamel.

LISBON, the capital of the kingdom of Portugal, situated in the province of Estremadura, on the banks of the river Tagus, in W. Long. 9. 25. N. Lat. 38. 25. It was anciently called *Olisippo*, *Olisippo*, and *Ulisippo*, which are supposed to be derived from the Phenician *Ulisubbo* or *Olisippo* signifying in that tongue a *pleasant bay*, such as that on which this city stands. It first became considerable in the reign of king Emmanuel; from that king it hath been the capital of the kingdom, the residence of its monarchs, the seat of the chief tribunals, and offices of the metropolitan, a noble university, and the receptacle of the richest merchandize of the East and West Indies. Its air is excellent; being refreshed by the delightful sea-breezes, and those of the Tagus. The city extends for about two miles along the Tagus; but its breadth is inconsiderable. Like old Rome, it stands on seven hills: but the streets in general are narrow and dirty, and some of them are very steep; neither are they lighted at night. The churches, in general, are very fine; but the magnificence of the chapel-royal is amazing. Here is one of the finest harbours in the world; and there were a great number

Lis.
Lisbon.

not only of fine churches and convents here, but also of other public buildings, and particularly of royal palaces, and others belonging to the grandes; but the greatest part of them, and of the city, were destroyed by a most dreadful earthquake, on Nov. 1. 1755, from which it will require a long time to recover. The inhabitants, before the earthquake, did not at most exceed 150,000. The government of it is lodged in a council, consisting of a president, six counsellors, and other inferior officers. The harbour has water enough for the largest ships, and room enough for 10,000 sail without being crowded. For its security, there is a fort at the mouth of the river, on each side, and a bar that runs across it, and is very dangerous to pass without pilots. Higher up, at a place where the river is considerably contracted, there is a fort called *Torre de Belem*, or the *Tower of Belem*, under whose guns all ships must pass in their way to the city; and on the other side are several more forts. Before the earthquake, most of the private houses were old and unsightly, with lattice-windows; and the number of convents and colleges amounted to 50, namely, 32 for monks and 18 for nuns. The king's principal palace stands on the river, and is large and commodious. Of the hospitals, that called the *Great* is obliged to receive all persons, of what degree, nation, or religion soever, without exception. At the village of Belem, near Lisbon, is a noble hospital for decayed gentlemen who have served the king, and have not wherewithal to maintain themselves. That called the *house of mercy* is also a noble charity. In the centre of the city, upon one of the highest hills, is the castle, which commands the whole, being large and ancient, and having always a garrison of four regiments of foot. The cathedral is a vast edifice of the Gothic kind, but heavy and clumsy: it contains, however, great riches, and is finely adorned within. The square called *Rosio* is large, and surrounded with magnificent buildings. The whole city is under the ecclesiastical jurisdiction of the patriarch, who was appointed in the year 1717. Here is also an archbishop, who has, or at least had before the erection of the patriarchate, a revenue of 40,000 crusades, or 6000 l. The university, which was removed for some time to Coimbra, but afterwards restored to its ancient seat, makes a considerable figure, though much inferior to that of Coimbra.

LISBURN, a town of Ireland, in the county of Antrim and province of Ulster, 73 miles from Dublin. It was burnt down about 50 years ago; but is now rebuilt in a neat and handsome manner, and has a large linen manufactory. It is seated on the river Laggan, in W. Long. 6. 20. N. Lat. 54. 31. It gives title of earl to the family of Vaughan; and it returns two members to parliament, one half of the patronage of this borough being in the earl of Hertford. Fairs held 21st of July and 5th of October.

LISEUX, a considerable town of France, in Upper Normandy, with a bishop's see. The churches and religious houses, and the bishop's palace, are all very handsome structures. It is a trading place; and is seated at the confluence of the rivers Arbeck and Gassin, in E. Long. 6. 20. N. Lat. 49. 11.

LISLE, a large, rich, handsome, and strong town of French Flanders, of which it is the capital, with a strong castle, and a citadel built by Vauban, and said Vol. X. Part I.

to be the finest in Europe, as well as the best fortified. The large square, and the public buildings, are very handsome; and they have manufactures of silks, cambrics, and camblets, as well as other stuffs, which have been brought to great perfection. It was taken by the duke of Marlborough, after three months siege and the loss of many thousands of men, in 1708; but restored to the French by the treaty of Utrecht, in consideration of their demolishing the fortifications of Dunkirk. It is seated on the river Ducle, 14 miles west of Tournay, 32 south-west of Ghent, 37 north-west of Mons, and 130 north of Paris, E. Long. 3. 9. N. Lat. 50. 38.

LISLE (Claudius de), a learned historiographer, born at Vancouleurs, in 1644. He studied among the Jesuits at Pontamousson; took his degrees in law, and afterwards applied himself intirely to the study of history and geography; and to perfect himself in those sciences went to Paris, where the principal lords of the court became his scholars, and among the rest the duke of Orleans, afterwards regent of the kingdom. He wrote, 1. An historical account of the kingdom of Siam. 2. A genealogical and historical Atlas. 3. An abridgement of universal history. He died at Paris in 1720.

LISLE (William de), son of the former, and the most learned geographer France has produced, was born at Paris in 1675. He became first geographer to the king, royal censor, and member of the academy of sciences. He died in 1726. He published a great number of excellent maps, and wrote many pieces in the memoirs of the academy of sciences.

LISLE (Sir John), a brave loyalist in the time of the civil wars, was the son of a bookseller in London, and received his education in the Netherlands. He signalized himself upon many occasions in the civil war, particularly in the last battle of Newbury; where, in the dusk of the evening, he led his men to the charge in his shirt, that his person might be more conspicuous. The king, who was an eye-witness of his bravery, knighted him in the field of battle. In 1648, he rose for his majesty in Essex; and was one of the royalists who so obstinately defended Colchester, and who died for the defence of it. This brave man having tenderly embraced the corps of Sir Charles Lucas, his departed friend, immediately presented himself to the soldiers who stood ready for his execution. "Thinking that they stood at too great a distance, he desired them to come nearer: one of them said, "I warrant you, Sir, we shall hit you." He replied with a smile, "Friends, I have been nearer you when you have missed me." He was executed August 28th 1648.

LISMORE, one of the Western islands of Scotland, seated at the mouth of Loch Linnhe, a capacious lake in Argyllshire, navigable for the largest ships to Fort William, which stands in the country called Lochaber. This island is above seven miles in length by one in breadth; and contains 1500 inhabitants. It abounds in limestone; from which, however, it has hitherto derived little advantage, owing to the want of good peat, the neglect of timber, and still more the duty upon coals. Thus, with the advantages of navigation in every direction, and of a soil lying upon the richest manure, the people are indigent, and frequently obliged to import meal for their subsistence. Many of

Lismore

them live a part of the year upon milk only. This island was formerly the residence of the bishops of Argle.

LISMORE, a borough, market, fair, and post town of Ireland, in the county of Waterford, and province of Munster, 100 miles from Dublin; N. Lat. 52. 5. W. Long. 7. 50. It was anciently called *Leshmore* or *Lios-more*, i. e. the great inclosure, or habitation; it is now a bishopric, and formerly had an university. St Carthagh or Mochuda, in the beginning of the seventh century founded an abbey and school in this place, which in a short time was much resorted to, not only by the natives, but also by the Britons and Saxons, during the middle ages. According to an ancient writer of the life of St Carthagh, Lismore was in general inhabited by monks, half of it being an asylum into which no woman dared enter; consisting intirely of cells and monasteries, the ruins of which, with seven churches, are yet visible. A castle was built here by king John. The site of Lismore was in early ages denominated *magh shia*, or the "chosen shield," being the situation of a din or fort, of the ancient chieftains of the Decies, one of whom granted it to St Carthagh on his expulsion from the abbey of Ratheny in Weitmeath. On becoming an university, Math Sgiath obtained the name of *Dunsginne*, or the "fort of the Saxons," from the number of Saxons which resorted thereto: but soon after, it was called *Lios-mor* or *Leshmore*, and now *Lismore*; the bishopric of which was united to that of Waterford in 1363, being 730 years after its foundation. The public road to Cork was formerly through this place, and at that time it had a better face of business. St Carthagh, who retired to this place with some of his religious in 636, to avoid the fury of the then Irish monarch, tied his disciples to a most strict rule of life; they never were allowed the use of flesh, fish, or fowl; only the vegetables that the ground produced at the expence of their own labour. Father Daniel, in his *Histoire Monastique*, mentions one on the same foundation in France. The castle here, which, as we have formerly mentioned, was built by king John, was erected in 1195 on the ruins of the abbey of St Carthagh; it belonged to the duke of Devonshire, and gave birth to the great philosopher Robert Boyle. In 1189 it was demolished by the Irish, who took it by surprise. Being afterwards re-edified, it was for many years an episcopal residence, till Myler Magrath, archbishop of Cashel, and bishop of this fee, granted the manor of Lismore to that noted scholar and soldier Sir Walter Raleigh, in the reign of queen Elizabeth, at the yearly rent of L. 13; 6; 8; but that estate was lopped off with his head in the reign of king James I. After which it fell into the hands of Sir Richard Boyle, who purchased all Sir Walter's lands; he beautified the whole, and added many buildings to it, most of which were burned down in the Irish rebellion; at the breaking out of which, it was closely besieged by 5000 Irish, commanded by Sir Richard Beling, and was well defended by the young Lord Broghill, third son of the earl of Cork, who obliged them to raise the siege. The castle is boldly seated on the verge of a rocky hill, rising almost perpendicularly to a considerable height over the river Blackwater. The entrance is by an ancient and venerable avenue of trees. Over the gate are the venerable arms

of the first earl of Cork. Opposite to the entrance is a modern portico of Bath stone, of the Doric order, designed by Inigo Jones. Most of the buildings have remained in ruins since the era of the rebellion; but the several offices that make up two sides of the square are kept in repair. At each angle is a tower, the chief remains of its former magnificence. In October 1785, the late duke of Rutland, then lord-lieutenant of Ireland, whilst on a tour in Munster, held a council in, and issued proclamations from this castle. The cathedral is still pretty well kept in repair. Here is a fine bridge over the river Blackwater, erected at a very great expence by the duke of Devonshire: this bridge is remarkable for the extent of the principal arch, the span of it being 102 feet. Below the town is a rich fishery for salmon, which is the greatest branch of trade here. Though this place is at present much reduced, yet Cambrensis informs us, that, not many years after the conquest, this was a very rich city, and held out some time against the English, who took it at last by storm, and gained rich plunder here, enough to load 16 sail of ships. It returns two members to parliament; patron, the duke of Devonshire, but the electors are called *potawollopers*. Fairs held on 25th May and September, and 12th November.

LISSA, an island in the Gulph of Venice, on the coast of Dalmatia, belonging to the Venetians, where they have a fishery of sardines and anchovies. It produces excellent wine, and is 70 miles west of Ragusa. E. Long. 17. 0. N. Lat. 43. 22.

LISSA, a town of Poland, in the palatinate of Pofna, of which it is the capital. E. Long. 16. 0. N. Lat. 32. 15.

LISSA, a village of Silesia, 16 miles from Breslau, remarkable for a battle fought between the Prussians and the Austrians on the 15th of December 1757, when the latter were entirely defeated.

LISSUS, (anc. geog.), the last town of Illyricum, towards Macedonia, situated on the Drilo. It had a capacious port, the work of Dionysius the Tyrant, who led the colony thither, enlarged and walled it round, (Diodorus Siculus.) Now called *Alessio*, in Albania, on the Drino, near the Gulph of Venice. E. Long. 20. N. Lat. 42.

LIST, in commerce, the border of cloth or stuff; serving not only to show their quality, but to preserve them from being torn in the operations of fulling, dyeing, &c.—List is used on various occasions; but chiefly by gardeners for securing their wall-trees.

LIST, in architecture, a little square moulding, otherwise called a *fillet*, *listel*, &c. See Plate XXXVIII. fig. 1.

LIST, is also used, to signify the inclosed field or ground wherein the ancient knights held their jousts and combats. It was so called, as being hemmed round with pales, barriers, or stakes, as with a list. Some of these were double, one for each cavalier; which kept them apart, so that they could not come nearer each other than a spear's length. See JUST, TOURNAMENT, DUEL, &c.

Civil LIST, in the British polity. The expences defrayed by the civil list are those that in any shape relate to civil government; as, the expences of the household; all salaries to officers of state, to the judges, and every one of the king's servants, the appointments to foreign

Lissa

Lit

Litany.

foreign ambassadors; the maintenance of the queen and royal family; the king's private expenses, or privy-purse; and other very numerous outgoings, as secret-service money, pensions, and other bounties: which sometimes have so far exceeded the revenues appointed for that purpose, that application has been made to parliament to discharge the debts contracted on the civil list; as particularly in 1724, when one million was granted for that purpose by the statute 11 Geo. I. c. 17. and in 1769, when half a million was appropriated to the like uses by the statute 9 Geo. III. c. 34.

The civil list is indeed properly the whole of the king's revenue in his own distinct capacity; the rest being rather the revenue of the public, or its creditors, though collected and distributed again in the name and by the officers of the crown: it now standing in the same place, as the hereditary income did formerly; and as that has gradually diminished, the parliamentary appointments have increased. The whole revenue of queen Elizabeth did not amount to more than 600,000*l.* a-year: that of king Char. I. was 800,000*l.* and the revenue voted for king Charles II. was 1,200,000*l.* though complaints were made (in the first years at least) that it did not amount to so much. But it must be observed, that under these sums were included all manner of public expenses; among which Lord Clarendon, in his speech to the parliament, computed, that the charge of the navy and land-forces amounted annually to 800,000*l.* which was ten times more than before the former troubles. The same revenue, subject to the same charges, was settled on king James II.: but by the increase of trade, and more frugal management, it amounted on an average to 1,500,000*l.* *per annum*, (besides other additional customs granted by parliament, which produced an annual revenue of 400,000*l.* out of which his fleet and army were maintained at the yearly expence of 1,100,000*l.* After the revolution, when the parliament took into its own hands the annual support of the forces both maritime and military, a civil-list revenue was settled on the new king and queen, amounting, with the hereditary duties, to 700,000*l.* *per annum*; and the same was continued to queen Anne and king George I. That of king Geo. II. was nominally augmented to 800,000*l.* and in fact was considerably more: but that of his present majesty is expressly limited to that sum; tho' 100,000*l.* hath been since added. And upon the whole, it is doubtless much better for the crown, and also for the people, to have the revenue settled upon the modern footing rather than the ancient. For the crown, because it is more certain, and collected with greater ease: for the people; because they are now delivered from the feudal hardships, and other odious branches of the prerogative. And though complaints have sometimes been made of the increase of the civil list, yet if we consider the sums that have been formerly granted, the limited extent under which it is now established, the revenues and prerogatives given up in lieu of it by the crown, the numerous branches of the present royal family, and (above all) the diminution of the value of money compared with what it was worth in the last century, we must acknowledge these complaints to be void of any rational foundation; and that it is impossible to support that dignity, which a king of Great Britain should maintain, with an income in any degree

less than what is now established by parliament. See REVENUE.

To LIST, or enlist, Soldiers, to retain and enroll men as soldiers, either as volunteers, or by a kind of compulsion. Persons lifted must be carried within four days, but not sooner than 24 hours after, before the next justice of peace of any county, riding, city, or place, or chief magistrate of any city or town corporate (not being an officer in the army); and if before such justice or magistrate they dissent from such enlisting, and return the enlisting-money, and also 20 shillings in lieu of all charges expended on them, they are to be discharged. But persons refusing or neglecting to return and pay such money within 24 hours, shall be deemed as duly listed as if they had assented thereto before the proper magistrate; and they shall, in that case, be obliged to take the oath, or, upon refusal, they shall be confined by the officer who lifted them till they do take it.

LISTER (Dr Martin), an eminent English physician and naturalist, was born in 1638, and educated at Cambridge. He afterwards travelled into France; and at his return practised physic at York, and afterwards at London. In 1683, he was created doctor of physic, and became fellow of the college of physicians in London. In 1698, he attended the earl of Portland in his embassy from king William III. to the court of France; of which journey he published an account at his return, and was afterwards physician to queen Anne. He also published, 1. *Historia animalium Anglie*, quarto. 2. *Conchyliorum synopsis*, folio. 3. *Cochlearum & limacum exercitatio anatomica*, 4 vols 8vo. 4. Many pieces in the Philosophical Transactions; and other works.

LISTOWEL, a parish, also a post and fair town, of Ireland, in the county of Kerry and province of Munster, 131. miles from Dublin, anciently *Lis Tuathal*, i. e. "the fort of Tuathal," who was exiled in the 1st century, but returned; and his life forms a brilliant era in Irish history. Near this are the ruins of a castle, pleasantly situated on the river Feale: it was taken in November 1600, by Sir Charles Wilmot, being then held out for the Lord Kerry against Queen Elizabeth. Five miles beyond Listowel are the ruins of a church. The fairs are three in the year.

LITANA SILVA (anc. geog.); a wood of the Boii, in the Gallia Togata, or Cispadana, where the Romans, under L. Posthumus Albinus (whose head the Boii cut off, and carried in triumph into their most sacred temple), had a great defeat, of twenty-five thousand scarce ten escaping (Livy). Hoffenius conjectures, that this happened above the springs of the Scultenna, in a part of the Apennine, between Cersinianum and Mutina. Now *Selva di Lugo*.

LITANY, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession, saying, *we beseech thee to hear us, good Lord, &c.* The word comes from the Greek *litanos*, "supplication" of *litanos*, "I beseech."

At first the use of litanies was not fixed to any stated time, but were only employed as exigencies required. They were observed, in imitation of the Ninevites, with ardent supplications and fastings, to avert the threatening judgments of fire, earthquakes, inundations,

Blackf.
Comment.* See Re-
venue.

Litchfield dations, or hostile invasions. About the year 400, litany began to be used in processions, the people walking barefoot, and repeating them with great devotion; and it is pretended, that by this means several countries were delivered from great calamities. The days on which these were used were called *rogation days*: these were appointed by the canons of different councils, till it was decreed by the council of Toledo, that they should be used every month throughout the year; and thus by degrees they came to be used weekly on Wednesdays and Fridays, the ancient stationary days for fasting. To these days the rubric of our church has added Sundays, as being the greatest days for assembling at divine service. Before the last review of the common prayer, the litany was a distinct service by itself, and used some time after the morning prayer was over; at present it is made one office with the morning-service, being ordered to be read after the third collect for grace, instead of the intercessional prayers in the daily service.

LITCHFIELD, a city of Staffordshire, in England, 117 miles from London. It stands low, about three miles from the Trent; and its ancient name is said to have been *Licidfield*, signifying, "a field of carcasses," from a great number of Christians having, as it is pretended, suffered martyrdom here in the persecution under Dioclesian. In the Saxons time, it was a bishoprick for a short space; and is now, together with Coventry, a bishoprick. It is divided into two parts by a rivulet and a kind of shallow lake, over which are two causeways with sluices. It is a long straggling place; but has some very handsome houses, and well-paved clean streets. That part on the south side of the rivulet is called the *city*, and the other the *close*. The *city* is much the largest, and contains several public structures. It was incorporated by Edw. VI. with the name of bailiffs and burgesses; and is both a town and county, governed by 2 bailiffs chosen yearly out of 24 burgesses, a recorder, a sheriff, a steward, and other officers. The city has power of life and death within their jurisdiction, a court of record, and a piepowder-court. Here is a gaol both for debtors and felons, a free school, and a pretty large well endowed hospital for a master and 12 brethren. The county of the city is 10 or 12 miles in compass, which the sheriff rides yearly on the 8th of September, and then feasts the corporation and neighbouring gentry. The *close* is so called from its being inclosed with a wall and a deep dry ditch on all sides except towards the city, where it is defended by a great lake or marsh formed by its brook. The cathedral, which stands in the close, was originally built by Oswius king of Northumberland about 300. It was rebuilt and enlarged by Offa king of Mercia in 766. In 1148 was rebuilt, and greatly enlarged in 1296. At the reformation, Coventry was divided from it. In the civil wars its spire was destroyed, and it converted to a stable. In 1776 a beautiful painted window, by the benefaction of Dr Adenbrook, has been set up at the western end of the cathedral. In the civil wars it was several times taken and retaken, and thereby suffered much; but was so repaired after the restoration, at the expence of 20,000 l. that it was one of the fairest and noblest structures of the kind in England. It is walled in like a castle, and stands so high as to be seen 10 miles round.

It is 450 feet long, of which the choir is 110, and the breadth in the broadest place 80. Its portico is hardly to be paralleled in England. There were till lately 26 statues of the prophets, apostles, kings of Judah, and some kings of this land, in a row above it, as big as the life; and on the top, at each corner of the portico, is a stately spire, besides a fine high steeple on the middle of the church. The choir is paved in great part with alabaster and channel-coal, in imitation of black and white marble. In 1789 it went under a general repair, when the massive groined arch betwixt the west end of the church and the transept, which had forced the side wall out of its perpendicular, was removed. The prebendaries stalls, which are thought to be the best in England, were most of them re-erected at the charge of the country gentlemen, whose names and arms are painted at the top of the stalls. The north door is extremely rich in sculpture, but much injured by time. The body, which is supported by pillars formed of numbers of slender columns, has lately had its decayed leaden roof replaced by a neat slated covering. The choir merits attention on account of the elegant sculpture about the windows, and the embattled gallery that runs beneath them; to which the altar-piece of Grecian architecture but ill corresponds; behind which is Mary's chapel, divided from it by a most elegant stone screen of beautiful workmanship. Here stood St Chad's shrine, which cost 2000 l. The charter-house is an octagon-room. In the same close are the palaces of the bishop and dean, and the prebendaries houses in a court on the hill. Here are three other churches; one of which, St Michael's, has a church-yard of 6 or 7 acres. There was a castle here, long since destroyed: and ancient camps have been discovered in its environs. In the neighbourhood are frequent horse-races. The markets there are on Tuesday and Friday, and six fairs in the year. By the late inland navigation, this place has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Cheshire, Warwick, Leicester, Oxford, Worcester, &c. Litchfield sends two members to parliament.

LITERARY, any thing belonging to LITERATURE.

LITERARY Property, or Copy-Right. See *COPY-RIGHT*. **LITERATI** (*letrados*, "lettered"), an epithet given to such persons among the Chinese as are able to read and write their language. The literati alone are capable of being made mandarins.

LITERATI is also the name of a particular sect, either in religion, philosophy, or politics, consisting principally of the learned men of that country; among whom it is called *jukiao*, i. e. "learned."

It had its rise in the year of Christ 1400, when the emperor, to awaken the native affection of the people for knowledge, which had been quite banished by the preceding civil wars among them, and to stir up emulation among the mandarins, chose out 42 of the ablest among their doctors, to whom he gave a commission to compose a body of doctrine agreeable to that of the ancients, which was then become the rule or standard of the learned. The delegates applied themselves to

the

thrax.

the business with very great attention; but some fancied them rather to have wrestled the doctrine of the ancients, to make it consist with theirs, than to have built up theirs on the model of the ancients.

They speak of the Deity, as if it were no more than mere nature or the natural power or virtue that produces, disposes, and preserves, the several parts of the universe. It is, say they, a pure, perfect principle, without beginning or end; it is the source of all things, the essence of every being, and that which determines it to be what it is. They make God the soul of the world: they say, he is diffused through all matter, and produces all the changes that happen there. In short, it is not easy to determine, whether they resolve God into nature, or lift up nature into God; for they ascribe to it many of those things which we attribute to God.

This doctrine, in lieu of the idolatry that prevailed before, introduced a refined kind of atheism. The work, being composed by so many persons of learning and parts, and approved by the emperor himself, was received with infinite applause by all the people. Many were pleased with it, because it seemed to subvert all religion; others approved it, because the little religion that it left them could not give them much trouble. And thus was formed the sect of the Literati; which consists of the maintainers and adherents to this doctrine.

The court, the mandarins, and the persons of fortune and quality, &c. are generally retainers to it; but a great part of the common people still hold to their worship of idols.

The literati freely tolerate the Mahometans, because they adore, with them, the king of heaven, and author of nature; but they bear a perfect aversion to all sorts of idolaters among them; and it was once resolved to extirpate them. But the disorder this would have occasioned in the empire prevented it: they now content themselves with condemning them, in general, as heretics; which they do solemnly every year at Pekin.

LITERATURE denotes learning or skill in letters.

LITERNUM. See LINTERNUM.

LITHANTHRAX, or *Pit-Coal*, is a black or brown, laminated, bituminous substance; not very easily inflammable, but, when once inflamed, burns longer and more intensely than any other substance. Of this substance three kinds are distinguished by authors. The residuum of the first after combustion is black; the residuum of the second is spongy, and like pumice-stone; and the residuum of the third is whitish ashes. Some fossil coal, by long exposure to air, falls into a greyish powder, from which alum may be extracted. Fossil coal by distillation yields, 1. a phlegm or water; 2. a very acid liquor; 3. a thin oil like naphtha; 4. a thicker oil, resembling petroleum, which falls to the bottom of the former, and which rises with a violent fire; 5. an acid concrete salt; 6. an uninflamable earth remains in the retort. These constituent parts of fossil-coal are very similar to those of amber and other bitumens. For the exciting of intense heats, as of furnaces for smelting iron-ore, and for operations where the acid and oily vapours would be detrimental, as the drying of malt, fossil-coals are previously charged, or reduced to coaks; that is, they are made to

Litharge
||
Litho-
mantia

undergo an operation similar to that by which charcoal is made. By this operation coals are deprived of their phlegm, their acid liquor, and the greatest part of their fluid oil. Coaks therefore consist of the two most fixed constituent parts, the heavy oil and the earth, together with the acid concrete salt, which the volatile is detained by the oil and earth.

LITHARGE, a preparation of lead, usually in form of soft flakes, of a yellowish reddish colour. If calcined lead be urged with a hasty fire, it melts into the appearance of oil, and on cooling concretes into litharge. Greatest part of the litharge met with in the shops is produced in the purification of silver from lead, and the refining of gold and silver by means of this metal: according to the degree of fire and other circumstances, it proves of a pale or deep colour; the first has been commonly called *litharge of silver*, the other *litharge of gold*. See CHEMISTRY-Index.

LITHGOW (William), a Scotman, whose sufferings by imprisonment and torture at Malaga, and whole travels, on foot, over Europe, Asia, and Africa, seem to raise him almost to the rank of a martyr and a hero, published an account of his peregrinations and adventures. Though the author deals much in the marvellous, the horrid account of the strange cruelties of which, he tells us, he was the subject, have, however, an air of truth. Soon after his arrival in England from Malaga, he was carried to Theobald's on a feather-bed, that King James might be an eye-witness of his *martyred anatomy*, by which he means his wretched body, mangled and reduced to a skeleton. The whole court crowded to see him; and his majesty ordered him to be taken care of, and he was twice sent to Bath at his expense. By the king's command, he applied to Gondamar, the Spanish ambassador, for the recovery of the money and other things of value which the governor of Malaga had taken from him, and for L. 1000 for his support. He was promised a full reparation for the damage he had sustained; but the perfidious minister never performed his promise. When he was upon the point of leaving England, Lithgow upbraided him with the breach of his word in the presence-chamber, before several gentlemen of the court. This occasioned their fighting upon the spot; and the ambassador, as the traveller oddly expresses it, had his fistula (with which disorder he was afflicted) contrabanded with his fist. The unfortunate Lithgow, who was generally condemned for his spirited behaviour, was sent to the Marshalsea, where he continued a prisoner nine months. At the conclusion of the octavo edition of his *Travels* he informs us, that, in his three voyages, "his painful feet have traced over (besides passages of seas and rivers) 36,000 and odd miles, which draweth near to twice the circumference of the whole earth." Here the marvellous seems to rise to the incredible; and to set him, in point of veracity, below Coryat, whom it is nevertheless certain that he far outwalked. His description of Ireland is whimsical and curious. This, together with the narrative of his sufferings, is reprinted in Morgan's *Phoenix Britannicus*.

LITHIASIS, or STONE. See MEDICINE-Index.

LITHOMANTIA, in antiquity, a species of divination performed with stones. Sometimes the stone, called *fiderius* was used: this they washed in spring-water.

water in the night by candle-light; the person that consulted it was to be purified from all manner of pollution, and to have his face covered: this done, he repeated divine prayers, and placed certain characters in an appointed order; and then the stone moved of itself, and in a soft gentle murmur, or (as some say) in a voice like that of a child, returned an answer. By a stone of this nature, Helena is reported to have foretold the destruction of Troy.

LITHONTRIPTICUS (from *λίθος* "a stone," and *τρύπτω* "to break"), an epithet for medicines that are supposed to break the stone in the bladder. Though the different stones that are generated in the human bladder require different solvents when out of the body; and though art hath not yet afforded a medicine which, when injected into the bladder, will, without injury thereto, dissolve the stone therein lodged; it cannot thence be concluded, that there are no lithontriptic medicines. It may be here observed, that one solvent affects one subject, but hath no effect on another; so a solvent may yet be met with that will destroy the stone, and not hurt the human body. The water into which the boiled white of egg dissolves will liquefy myrrh, but may be put into the human eye without causing any uneasiness.

Soap ley taken at first in small doses in broth that is freed from all its fat, succeeds in most cases which require an alkaline solvent. The patient may begin with 20 drops, and gradually increase the dose as he is able; and by repeating it three times a-day for six, eight, or twelve months, the wished for effects often follow.

LITHOPHYTA, the name of Linnæus's third order of vermes. See **ZOOLOGY**.

LITHOSPERMUM, GROWELL: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 4th order, *Asperifolia*. The corolla is funnel-shaped, with the throat perforated and naked; the calyx quinquepartite. There are several species; but the only remarkable ones are the officinale or common growwell, and the arvense or bastard alkanet. Both these are natives of Britain; the former growing in dry gravelly soil, the latter in corn-fields. The seeds of the first are reputed to be of service in calculous cases. Dr Grew says, that they have so much earth in their composition, that they effervesce with acids; but if this is the case, it must be attributed rather to an alkaline than an earthy quality.

LITHOSTROTION, in natural history, the name of a species of fossil coral, composed of a great number of long and slender columns, sometimes round, sometimes angular, jointed nicely to one another, and of a starry or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens. See **PLATE CC**.

LITHOSTROTON, among the Romans, was a pavement of Mosaic work, consisting of small pieces of cut marble of different kinds and colours. The *lithostrota* began to be used in the time of Sylla, who made one at Præneste in the temple of Fortune. At last they were used in private houses; and were brought to such perfection, that they exhibited most lively re-

presentations of nature, with all the exactness of the finest painting.

LITHOTOMY, in surgery, the operation of cutting for the stone. See **SURGERY**.

LITHUANIA, an extensive province of Poland. By the natives it is called *Letwa*, and has Great Poland and Russia on the west; part of Muscovy on the east; Livonia, the Baltic Sea, and part of Muscovy, on the north; Red Russia, Volhnia, and Padolia, on the south; and the Ukraine on the south-east. Its length is said to be about 360, and its breadth 340 miles; but it is much indented both ways. Lithuania was anciently over-run with wood; and there are still many forests in it, which yield a great deal of honey, wax, pitch, tar, and timber; and abound with wild boars, buffaloes, elks, wild horses, wild asses, uri, and woodcocks. The lakes are also numerous, and well-flored with fish; but the air, by reason of these forests and lakes, is said to be thick and foggy. The country produces a great deal of buck-wheat and other corn, the pastures are luxuriant, and the flocks and herds numerous: so that, notwithstanding agriculture is much neglected, provisions are exceeding cheap, but money so scarce, that 10 per cent. is the common interest. The principal nobility have large estates, and live in great pomp and splendor, generally retaining some hundreds of those that are poor, in quality of domestics. The established religion is Popery; but Lutherans, Calvinists, Jews, Turks, Greeks, and Socinians, are very numerous. Lithuania was governed by its own dukes till it was united to Poland, towards the end of the 14th century, when the great Duke Jagello married Hedwig, the dowager of Louis king of Poland and Hungary. It had even dukes after that, but they were subordinate to the king; and at this day, tho' one diet serves for both countries, yet each has its peculiar laws, customs, dialect, and privileges. In a diet held at Lublin in 1569, it was more closely united to Poland than it had been before; and it was enacted, that both countries, for the future, should form but one state under the same prince. As to their courts of justice, the tenth part of what is adjudged in all real actions goes always to the judge's box, and is immediately paid in court; and in personal actions he claims half the damages given. A nobleman is only fined for murder, as in Poland. The common people here, excepting the burghers in the royal towns, and the Germans, are slaves; and, in many places, the ignorant vulgar still retain some remains of idolatry. The poor people have only Mondays to themselves; and if their lords have occasion for them even on that day, the peasant must work for himself on Sunday. If any of them is condemned to death by his lord, he must execute himself, or suffer greater cruelty. The dialect is a language of the Slavonic; and they speak here, as in Poland, a barbarous kind of Latin. Lithuania is divided into nine palatinates. Another division is into Lithuanian properly so called, and Lithuanian Russia. Some also comprehend under it Samogitia and Courland, which is a sief of Poland.

LITMUS, or **LACMUS**, in the arts, is a blue pigment, formed from *archil*. It is brought from Holland at a cheap rate; but may be prepared by adding quick

Litter
||
Littleton.

quick lime and putrified urine, or spirit of urine distilled from lime, to the archil previously bruised by grinding. The mixture having cooled, and the fluid suffered to evaporate, becomes a mass of the consistence of a paste, which is laid on boards to dry in square lumps. It is only used in miniature paintings, and cannot be well depended on, because the least approach of acid changes it instantly from blue to red. The best litmus is very apt to change and fly.

LITTER (*littera*), a kind of vehicle borne upon shafts; anciently esteemed the most easy and genteel way of carriage. Du-Cange derives the word from the barbarous Latin *litteria* "straw or bedding for beasts." Other will rather have it come from *latus* "bed;" there being ordinarily a quilt and a pillow to a litter in the same manner as to a bed.

Pliny calls the litter the *traveller's chamber*: it was much in use among the Romans, among whom it was borne by slaves kept for that purpose; as it still continues to be in the east, where it is called a *palanquin*.—The Roman *littera*, made to be borne by four men, was called *tetraphorum*; that borne by six *hexaphorum*; and that borne by eight *octaphorum*.

The invention of litters, according to Cicero, was owing to the kings of Bithynia: in the time of Tiberius they were become very frequent at Rome, as appears from Seneca; and even slaves themselves were borne in them, though never by more than two persons, whereas men of quality had six or eight.

LITTER also denotes a parcel of dry old straw put on the floor of a horse's stall for him to lie down and rest upon. When a horse comes tired into a stable, fresh litter has the virtue of making him stale immediately. This is known to be a very great advantage to a horse in a tired state; and when the litter is old and dirty, it never has any such effect upon him. If the owners knew how refreshing it is for a horse to discharge his urine on his return from labour, they would be more careful of giving them all means and occasions of it than they are. This staling after fatigue prevents those obstructions in the neck of the bladder or urinary passages which horses are too subject to. The bladder being often inflamed by the long retention of the heated urine in it, the creature is thus in danger of perishing.

LITTLE (William), an ancient English historian, known also by the name of *Gulielmus Neubrigenfis*, was born at Bridlington in the county of York, in the year 1136; and educated in the abbey of Newborough in the same county, where he became a monk. In his advanced years, he composed a history of England, in five books, from the Norman conquest to A. D. 1197; which, for veracity, regularity of disposition, and purity of language, is one of the most valuable productions of this period.

LITTLETON (Sir Thomas), judge of the common-pleas, was the eldest son of Thomas Westcote, esq; of the county of Devon, by Elizabeth, sole heiress of Thomas Littleton of Frankley in Worcestershire, at whose request he took the name and arms of that family. He was educated at one of our universities, probably at Cambridge. Thence he removed to the Inner Temple, where he became one of the readers; and was afterwards, by Henry VI. made steward or judge of the court of the palace, or marshalsea of the king's household. In 1455, the thirty-

third of that reign, he was appointed king's serjeant, and rode the northern circuit as judge of assize. In 1462, the second of Edward IV. he obtained a pardon from the crown; and, in 1466, was appointed one of the judges of the common-pleas, and rode the Northamptonshire circuit. In the year 1474 he was, with many of the first nobility, created knight of the Bath. He died in 1481; and was buried in the cathedral church of Worcester, where a marble tomb, with his statue upon it, was erected to his memory. As to his character as a lawyer, it is sufficient to inform the reader, that he was the author of the Treatise upon Tenures, on which Sir Edward Coke wrote a comment, well known by the title of *Coke upon Littleton*.

LITTLETON (Adam), descended from an ancient family in Shropshire, was born in 1627, educated at Westminster-school, and went to Oxford a student of Christ-church, whence he was ejected by the parliament visitors in 1648. Soon after, he became usher of Westminster-school, and in 1658 was made second master of Westminster-school. After the restoration he taught a school at Chelsea in Middlesex, of which church he was admitted rector in the year 1664. In 1670 he accumulated the degrees in divinity, being then chaplain in ordinary to his majesty. In 1674, he became prebendary of Westminster, of which church he was afterwards sub-dean. Beside the well-known *Latin and English Dictionary*, he published several other works. He died in 1694, and was interred at Chelsea. He was an universal scholar; and extremely charitable, humane, and easy of access.

LITURGY, denotes all the ceremonies in general belonging to divine service.

The word comes from the Greek *λειτουργία* "service, public ministry;" formed of *λειτουργ* "public," and *εργον* "work."

In a more restrained signification, liturgy is used among the Romanists to signify the *mass*; and among us the *common-prayer*.

All who have written on liturgies agree, that in the primitive days divine service was exceedingly simple, only clogged with a very few ceremonies, and consisting of but a small number of prayers; but, by degrees, they increased the number of external ceremonies, and added new prayers, to make the office look more awful and venerable to the people. At length things were carried to such a pitch, that a regulation became necessary; and it was found proper to put the service, and the manner of performing it, into writing; and this was what they called a *liturgy*.

Liturgies have been different at different times, and in different countries. We have the liturgy of St Chrysostom, that of St Peter, of St James, the liturgy of St Basil, the Armenian liturgy, the liturgy of the Maronites, of the Copts, the Roman liturgy, the Gallican liturgy, the English liturgy, the Ambrosian liturgy, the Spanish and African liturgies, &c.

In the more early ages of the church, every bishop had a power to form a liturgy for his own diocese; and if he kept to the analogy of faith and doctrine, all circumstances were left to his own discretion. Afterwards the practice was for the whole province to follow the metropolitan church, which also became the general rule of the church: and this Lindwood acknowledges

Liturgy.

Liturg
||
Livadia.

lidges to be the common law of the church; intimating, that the use of several services in the same province, which was the case in England, was not to be warranted but by long custom. The liturgy of the church of England was composed in the year 1547, and established in the second year of King Edward VI. stat. 2. and 3 Ed. VI. cap. 1.

In the fifth year of this king it was reviewed; because some things were contained in that liturgy which shewed a compliance with the superstition of those times, and some exceptions were taken against it by some learned men at home, and by Calvin abroad. Some alterations were made in it, which consisted in adding the general confession and absolution, and the communion to begin with the ten commandments. The use of oil in confirmation and extreme unction were left out, and also prayers for souls departed, and what tended to a belief of Christ's real presence in the eucharist. This liturgy, so reformed, was established by the act of 5 and 6 Ed. VI. cap. 1. However, it was abolished by Queen Mary, who enacted, that the service should stand as it was most commonly used in the last year of the reign of King Henry VIII. The liturgy of 5 and 6 Ed. VI. was re-established with some few alterations and additions, by 1 Eliz. cap. 2. Some farther alterations were introduced, in consequence of the review of the common prayer-book, by order of King James, in the first year of his reign; particularly in the office of private baptism, in several rubrics and other passages, with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of common-prayer, so altered, remained in force from the first year of King James to the fourteenth of Charles II. But the last review of the liturgy was in the year 1661, and the last act of uniformity enjoining the observance of it is 13 and 14 Car. II. cap. 4. See *COMMON-PRAYER*. Many applications have been since made for a review, but hitherto without success.

LITUUS, among the Romans, was the staff made use of by the augurs in quattering the heavens. It bore a great resemblance to the crozier of a bishop, but was shorter. It was crooked at one end, and thickest in the curved part, according to A. Gellius. We frequently meet with a representation of it upon medals, amongst other pontifical instruments. It was called *Lituus Quirinalis*, from Quirinus, a name of Romulus, who was skilled in all the mysteries of augury.

LITRUS, was also an instrument of music in use in the Roman army. It was straight, excepting that it had a little bending at the upper end like a lituus or sacred staff of the augurs; and from the similitude it derived its name. The litrus, as an instrument of martial music, was of a middle kind, betwixt the cornu and the tuba.

LIVADIA, anciently *Achaia* and *Hellas*, or *Greece* properly so called; a province of Turkey in Europe, bounded on the north by Epirus and Thessaly, from which is separated by mount Oeta, now Banina, and by the Euripus, now the strait of Negropont; on the east, by the Archipelago; on the south, by the gulf of Engia or Egina, the isthmus of Corinth, and the N^o 183.

Livadia
||
Liver.

gulf of Lepanto; and on the west, by the Ionian sea and part of Epirus. Its extent is about 130 miles from north-west to south-east; but its greatest breadth is not above 36 miles. It is in general a mountainous country; but neither unpleasant nor unfruitful. The principal mountains are, mount Oeta in Bœotia, where is the famous pass of Thermopylæ, not above 25 feet broad; and Parnassus, Helicon, and Cythæron in Phocis, which were sacred to Apollo and the muses, and consequently much celebrated by the poets. The rivers of most note are, the Sionapros, anciently the Achelous, the Cephissus, the Ifimenus, and the Afopos. The province is at present divided into Livadia proper, Stramulippa, and the duchy of Athens. The principal places are, Lepanto, anciently Naupactus; Livadia, anciently Libadia or Lebada; the celebrated city of Athens, now Setines; Thebes, now Stibes; Lepina, anciently Eleusis; Castri, formerly Delphi; and Megara.

LIVADIA, an ancient town of Turkey in Europe, and capital of a province of the same name in Greece. It is a large and populous place, seated on the gulf of Lepanto, about 25 miles from the city of that name. It has now a considerable trade in woollen stuffs and rice. Anciently it was celebrated for the oracle of Trophonius, which was in a cavern in a hill above the town. E. Long. 23. 29. N. Lat. 38. 40.

LIVER, in anatomy. See there, n^o 96.—Plato, and other of the ancients, fix the principle of love in the liver; whence the Latin proverb, *Cogit amare jecur*: and in this sense Horace frequently uses the word, as when he says, *Si torrere jecur queris Idonæum*.—The Greeks, from its concave figure, called it *σπῆν*, “ vaulted, suspended;” the Latins call it *jecur*, q. d. *juxta cor*, as being “near the heart.” The French call it *foie*, from *foyer*, *focus*, “a fire-place;” agreeable to the doctrine of the ancients, who believed the blood to be boiled and prepared in it.—Erasistratus, at first, called it *parenchyma*, i. e. *effusion*, or *mass of blood*; and Hippocrates, by way of eminence, frequently calls it the *hypochondrium*.

LIVER of Antimony. See *CHEMISTRY-Index*.

LIVER of Arsenic, is a combination of white arsenic with liquid fixed vegetable alkali, or by the humid way. Arsenic has in general a strong disposition to unite with alkalis. Mr Maquer, in his *Mémoires upon Arsenic*, mentions a singular kind of neutral salt, which results from the union of arsenic with the alkaline basis of nitre, when nitre is decomposed, and its acid is disengaged in close vessels, by means of arsenic. To this salt he has given the name of *neutral arsenical salt* †. † See *Chem. Index*. The liver of arsenic, mentioned also by that chemist, although composed, like the neutral arsenical salt, of arsenic and fixed alkali, is nevertheless very different from that salt.

The operation for making liver of arsenic is easy and simple. To strong and concentrated liquid fixed alkali, previously heated, fine powder of white arsenic must be added. This arsenic easily disappears and dissolves, and as much of it is to be added till the alkali is saturated, or has lost its alkaline properties, although it is still capable of dissolving more arsenic superabundantly. While the alkali dissolves the arsenic in this operation, it

Liver,
Liverpool.

it acquires a brownish colour, and a singular and disagreeable smell; which, however, is not the smell of pure arsenic heated and volatilized. Lastly, this mixture becomes more and more thick, and at length of a gluey consistence. This matter is not crystallizable as the neutral arsenical salt is. It is easily decomposed by the action of fire, which separates the arsenic. This does not happen to the arsenical salt. Any pure acid is capable of separating arsenic from the liver of arsenic, in the same manner as they separate sulphur from liver of sulphur: whereas the neutral arsenical salt cannot be decomposed but by means of the united affinities of acids and metallic substances. Thus we see that arsenic may be combined with fixed alkali in two very different manners.

The author has given to this combination the name of *liver of arsenic*, to distinguish it from the neutral arsenical salt, and in imitation of the name of the *liver of sulphur*, given to the combination of the fixed alkali with sulphur.

LIVER of Sulphur. See CHEMISTRY, Index.

LIVER-Wort, in botany. See MARCHANTIA and LICHEN.

LIVER-Stone, (lapis hepaticus); a genus of inflammable substances, containing, besides its phlogiston, argillaceous, ponderous, and siliceous earth, united with vitriolic acid. See EARTHS, §. 1. n. 4.

Mr Bergman, in his *Sciagraphia*, informs us, that 100 parts of this stone contain 33 of siliceous earth, 29 of caustic ponderous earth, almost 5 of argillaceous earth, and 3.7 of lime, besides the vitriolic acid and water of crystallization: but Mr Kirwan quotes another analysis of the same author, where it is said that 100 parts of it contain 33 of baro-felenite, 38 of siliceous earth, 22 of alum, 7 of gypsum, and 5 of mineral oil.

LIVERPOOL, a large, flourishing, and populous town of England, in the county of Lancaster, situated at the influx of the river Mersey into the sea. This town has so much increased in trade since the commencement of the present century, that it is now the greatest sea-port in England except London, having exceeded Bristol considerably of late years; which will appear by the following account of the custom-duties, received in the several ports of London, Liverpool, and Bristol, in the year 1784, taken from the report of the commissioners for inspecting the state of public accounts.

London,	-	-	-	L. 5,187,052	9	5 $\frac{1}{2}$
Liverpool,	-	-	-	640,684	2	2 $\frac{1}{2}$
Bristol,	-	-	-	334,909	19	3 $\frac{1}{2}$

Liverpool exceeded Bristol, L. 3,57,774 2 11

The following shows how much the trade has increased since the above period:

Duties received in the port of Liverpool from July 5th 1787, to October 11th 1787. L. 298,361 9 10 $\frac{1}{2}$. The merchants here trade to all parts of the world except Turkey and the East Indies; but the most beneficial trade is to Guinea and the West Indies, by which many of them have acquired very large fortunes.

Liverpool, during the last war, carried on more foreign trade than any town in England; and such is the

state of it at this time, that there are near three thousand vessels cleared from that port in one year to different parts of the world. Here are several manufactories for China-ware, and pot-houses which make very fine ware, some salt-works, glass-houses, and upwards of 50 breweries, from some of which large quantities of malt-liquor are sent abroad. Many of the buildings are formed in the most elegant manner; but the old streets are narrow; which defect will soon be removed, as the corporation have lately obtained an act of parliament for the improvement of the town, which they have already begun to put in force with great spirit, having taken down the principal streets in the centre of the town, and rebuilt them in a spacious and most magnificent manner; so that in a few years it will be one of the handsomest towns in England. This town contains ten churches, namely, St Peter's, St Nicholas's, St George's, St Thomas's, St Paul's, St Ann's, St John's, St James's, St Catharine's, and St Mary's. There are also meetings for independents, anabaptists, quakers, methodists, and presbyterians. The exchange is a noble structure, built of white stone in the form of a square, and round it are piazzas where the merchants assemble to transact business. Above it are the mayor's offices, the sessions-hall, the council-chamber, and two elegant ball-rooms. The expence of erecting this building amounted to L. 30,000. The custom-house is situated at the head of the old dock, and is a handsome and convenient structure. Here are many charitable foundations, among which is an excellent grammar-school well endowed, and many of the youth taught in it have exhibitions in the universities. The infirmary is a large edifice of brick and stone, situated on a hill in a very pleasant airy situation, at one end of the town.

In the town is a charity-school supported by voluntary subscriptions and contributions for 50 boys and 12 girls, who are not only clothed and educated, but also provided with food and lodging: likewise several alms houses for the widows of seamen; and an excellent poor-house, superior to any in the kingdom, where upwards of 800 men, women, and children, are supported, many of whom are employed in spinning cotton and wool. There are five large wet docks, three dry docks, and several graving docks for the repairing of shipping; which renders it the most commodious sea-port in the world. The quays which bound these docks are covered with warehouses; which is a convenience that enables the merchant to discharge his ship at a very small expence. The new prison lately finished is a noble edifice, being built entirely on the plan of the great and benevolent Mr Howard, for solitary confinement; and is perhaps the most convenient, airy, magnificent building of the kind in Europe; being upon a very extensive scale.

Liverpool received its charter from king John: it is under the government of a recorder, mayor, and an unlimited number of aldermen, two bailiffs, and a common-council of forty of the principal inhabitants, with a town-clerk and other proper officers. The town has a weekly market on Saturday, and is distant from London 204 miles. The progressive rise of population

Liverpool, tion in Liverpool, may be conceived by perusing the following table:

Year.	Christened.	Buried.	Married.
1660	3	—	—
1680	106	51	5
1700	132	124	35
1720	410	293	58
1740	485	668	137
1760	986	599	408
1780	1769	1544	606
1787	2267	1773	804

By the late inland navigation, Liverpool has communication with the rivers Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester, &c. The Mersey, upon which the town is situated, abounds with salmon, cod, flounders, turbot, plaice, and smelts; and at full sea it is above two miles over. In the neighbourhood are frequent horse-races, on a five-mile course, the finest for the length in England. The soil in and near the town is dry and sandy, and particularly favourable to the growth of potatoes, on which the farmers often depend more than on wheat or any other grain. Fresh water is brought into the town by pipes, from some springs four miles off, pursuant to an act of parliament in the reign of Queen Anne. Liverpool sends two members to parliament.

LIVERY, in matters of dress and equipage, a certain colour and form of dress, by which noblemen and gentlemen choose to distinguish their servants.

Liveries are usually taken from fancy, or continued in families by succession. The ancient cavaliers, at their tournaments, distinguished themselves by wearing the liveries of their mistresses: thus people of quality make their domestics wear their livery.

Father Menestrier, in his *Treatise of Carousals*, has given a very ample account of the mixtures of colours in liveries. Dion tells us, that Oenomaus was the first who invented green and blue colours, for the troops which, in the circus, were to represent land and sea-fights.

The Romish church has also her several colours and liveries; white, for confessors and virgins, and in times of rejoicing; black, for the dead; red, for the apostles and martyrs; blue or violet, for penitents; and green, in times of hope.

Formerly, great men gave liveries to several, who were not of their family or servants, to engage them in their quarrels for that year; but this was prohibited by the statutes 1 Rich. II. 1 Hen. IV. cap. 27. 2 and 7 Hen. IV. 8 Hen. VI. cap. 4. 8 Ed. IV. cap. 2; and no man, of whatever condition, was allowed to give any livery, but to his domestic officers, and council learned in the law. However, most of the above statutes are repealed by 3 Car. I. cap. 4.

Livest of Selfin, in-law, signifies delivering the

possession of lands, &c. to him who has a right to Livest. Livius.

LIVERYMEN of London, are a number of men chosen from among the freemen of each company. Out of this body the common-council, sheriff, and other superior officers for the government of the city, are elected; and they alone have the privilege of giving their votes for members of parliament, from which the rest of the citizens are excluded.

LIVIVS (Titus), the best of the Roman historians, as he is called by Mr Bayle, was born at Patavium, or Padua. Few particulars of his life have been handed down to us. Coming to Rome, he acquired the notice and favour of Augustus, and there he long resided. Some have supposed, (for there is not any proof of it), that he was known to Augustus before, by certain Philosophical Dialogues which he had dedicated to him. Seneca says nothing of the dedication; but mentions the dialogues, which he calls historical and philosophical; and also some books, written purposely on the subject of philosophy. Be this as it will, it is probable that he began his history as soon as he was settled at Rome; and he seems to have devoted himself so entirely to the great work he had undertaken, as to be perfectly regardless of his own advancement. The tumults and distractions of Rome frequently obliged him to retire to Naples; not only that he might be less interrupted in the pursuit of his destined task, but also enjoy that retirement and tranquillity which he could not have at Rome, and which yet he seems to have much sought after: for he was greatly disatisfied with the manners of his age, and tells us, that "he should reap this reward of his labour, in composing the Roman history, that it would take his attention from the present numerous evils, at least while he was employed upon the first and earliest ages." He used to read parts of this history, while he was composing it, to Mæcenas and Augustus; and the latter conceived so high an opinion of him, that he pitched upon him to superintend the education of his grandson Claudius, who was afterwards emperor. After the death of Augustus, Livy returned to the place of his birth, where he was received with all imaginable honour and respect; and there he died, in the fourth year of the reign of Tiberius, aged above seventy. Some say, he died on the same day with Ovid: it is certain that he died the same year.

Scarce any man was ever more honoured, alive as well as dead, than this historian. Pliny the younger relates, that a native gentleman travelled from Gades, in the extremest parts of Spain, to see Livy; and, though Rome abounded with more stupendous and curious spectacles than any city in the world, yet he immediately returned; as if, after having seen Livy, nothing farther could be worthy of his notice. A monument was erected to this historian in the temple of Juno, where was afterwards founded the monastery of St Justina. There, in 1413, was discovered the following epitaph upon Livy: *Ossa Titi Livii Patavini, omnium mortalium judicio digni, cujus prope invictio calamo invidi populi Romani res gesta conscriberentur*; that is, "The bones of Titus Livius of Patavium, a man worthy to be approved by all mankind, by whose almost invincible pen the acts and exploits of the invincible Romans

Livius. mans were written." These bones are said to be preserved with high reverence to this day, and are shown by the Paduans as the most precious remains. In 1451, Alphonsus, king of Arragon, sent his ambassador, Anthony Panormita, to desire of the citizens of Padua the bone of that arm with which this their famous countryman had written his history: and, obtaining it, caused it to be conveyed to Naples with the greatest ceremony as a most invaluable relic. He is said to have recovered from an ill state of health by the pleasure he found in reading this history: and therefore, out of gratitude, put upon doing extraordinary honours to the memory of the writer. Panormita also, who was a native of Palermo in Sicily, and one of the ablest men of the 15th century, sold an estate to purchase this historian.

The history of Livy, like other great works of antiquity, is transmitted down to us exceedingly mutilated and imperfect. Its books were originally an hundred and forty-two, of which are extant only thirty-five. The epitomes of it, from which we learn their number, all remain, except those of the 136th and 137th books. Livy's books have been divided into decades, which some will have to have been done by Livy himself, because there is a preface to every decade; while others suppose it to be a modern contrivance, since nothing about it can be gathered from the ancients. The first decade, beginning with the foundation of Rome, is extant, and treats of the affairs of 460 years. The second decade is lost; the years of which are seventy-five. The third decade is extant, and contains the second Punic war, including eighteen years. It is reckoned the most excellent part of the history, as giving an account of a very long and sharp war, in which the Romans gained so many advantages, that no arms could afterwards withstand them. The fourth decade contains the Macedonian war against Philip, and the Asiatic war against Antiochus, which takes up the space of about 23 years. The five first books of the fifth decade were found at Worms, by Simon Gryneus, in 1431, but are very defective; and the remainder of Livy's history, which reaches to the death of Drusus in Germany in 746, together with the second decade, are supplied by Freinhemius.

Never man perhaps was furnished with greater advantages for writing a history than Livy. Besides his own great genius, which was in every respect admirably formed for the purpose, he was trained as it were in a city, at that time the empress of the world, and in the politest reign that ever was; having scarcely had any other school than the court of Augustus. He had access to the very best materials, such as the Memoirs of Sylla, Cæsar, Labienus, Pollio, Augustus, and others, written by themselves. "What writers of memorials (says Lord Bolingbroke), what compilers of the *Matéria Historica*, were these! What genius was necessary to finish up the pictures that such masters had sketched! Rome afforded men that were equal to the task. Let the remains, the precious remains, of Salust, of Livy, and of Tacitus, witness this truth. — What a school of public and private virtue had been opened to us at the resurrection of learning, if the latter historians of the Roman commonwealth, and the first of the succeeding monarchy, had come down to us entire! The few that are come down, though broken and imperfect, compose the best body of history that

we have; nay, the only body of ancient history that deserves to be an object of study. It fails us indeed most at that remarkable and fatal period, where our reasonable curiosity is raised the highest. Livy employed forty-five books to bring his history down to the end of the sixth century, and the breaking out of the third Punic war: but he employed ninety-five to bring it down from thence to the death of Drusus; that is, through the course of 120 or 130 years. Appian, Dion Cassius, and others, nay, even Plutarch included, make us but poor amends for what is lost of Livy." Speaking then of Tully's orations and letters, as the best adventitious helps to supply this loss, he says, that "the age in which Livy flourished, abounded with such materials as these: they were fresh, they were authentic: it was easy to procure them; it was safe to employ them. How he did employ them in executing the second part of his design, we may judge from his execution of the first; and, I own, I should be glad to exchange, if it were possible, what we have of this history for what we have not. Would you not be glad, my lord, to see, in one stupendous draught, the whole progress of that government from liberty to servitude; the whole series of causes and effects, apparent and real, public and private?" &c.

The encomiums bestowed upon Livy, by both ancients and moderns, are great and numerous. He not only entertains like Herodotus; he also instructs and interests in the deepest manner. But the great probity, candour, and impartiality, are what have distinguished Livy above all historians; for neither complaisance to the times, nor his particular connections with the emperor, could restrain him from speaking well of Pompey; so well, as to make Augustus call him a *Pompeian*. This we learn from Crematius Cordus, in Tacitus; who relates also, much to the emperor's honour, that this gave no interruption to their friendship. But whatever eulogies Livy may have received as an historian, he has not escaped censure as a writer. In the age wherein he lived, Asinius Pollio charged him with Patavinity; which Patavinity has been variously explained by various writers, but is generally supposed to relate to his style. The most common is, that this noble Roman, accustomed to the delicacy of the language spoken in the court of Augustus, could not bear with certain provincial idioms, which Livy, as a Paduan, used in divers places of his history. Pignorius is of another mind, and believes that this Patavinity regarded the orthography of certain words, wherein Livy used one letter for another, according to the custom of his country, writing *sibi* and *quæle* for *sibi* and *quasi*; which he attempts to prove by several ancient inscriptions. The expressions, however, or the orthography of words, are not loaded with obscurity, and the perfect classic is as familiarly acquainted with those supposed provincialisms as with the purest Latinity. — Livy has been censured too, and perhaps with justice, for being too credulous, and burdening his history with vulgar notions and superstitious tales. He may disgust when he mentions that milk and blood were rained from heaven, or that an ox spoke or a woman changed her sex; yet he candidly confesses that he recorded only what made an indelible impression upon the minds of a credulous age.

Is it worth while to mention here the capricious

Livius.

and tyrannic humour of the emperor Caligula, who accused Livy of being a negligent and wordy writer, and resolved therefore to remove his works and statues out of all libraries, where he knew they were curiously preserved? Or the same humour in Domitian, another prodigy of nature, who put to death Metius Pomponianus, because he made a collection of some orations of kings and generals out of Livy's history? Pope Gregory the Great, also, would not suffer Livy in any Christian library, because of the Pagan superstition wherewith he abounded: but the same reason held good against all ancient authors; and indeed Gregory's zeal was far from being levelled at Livy in particular, the pontiff having declared war against all human learning.

Though we know nothing of Livy's family, yet we learn from Quintilian, that he had a son, to whom he addressed some excellent precepts in rhetoric. An ancient inscription speaks also of one of his daughters, named *Livia Quaria*: the same, perhaps, that espoused the orator Lucius Magius, whom Seneca mentions; and observes, that the applauses he usually received from the public in his harangues, were not so much on his own account, as for the sake of his father in law.

Our author's history has been often published with and without the supplement of Freinsheimius. The best editions are, that of Gronovius, *cum notis variorum & suis*, Lugd. Bat. 1679, 3 vol. 8vo; that of Le Clerc, at Amsterdam, 1709, 10 vol. 12mo; and that of Crevier, at Paris, 1735, 6 vol. 4to. These have the supplements.—Learning perhaps never sustained a greater loss, in any single author, than by the destruction of the latter and more interesting part of Livy. Several eminent moderns have indulged the pleasing expectation that the entire work of this noble historian might yet be recovered. It has been said to exist in an Arabic version: and even a complete copy of the original is supposed to have been extant as late as the year 1631, and to have perished at that time in the plunder of Magdeburgh. The munificent patron of learning, Leo X. exerted the most generous zeal to rescue from oblivion the valuable treasure, which one of his most bigotted predecessors, above mentioned, had expelled from every Christian library. Bayle has preserved, under the article Leo, two curious original letters of that pontiff, concerning his hopes of recovering Livy; which afford most honourable proofs of his liberality in the cause of letters.—A lately discovered fragment of Livy's history was published in 1773 by Dr Bruns.

LIVIVS (Andronicus), a comic poet who flourished at Rome about 240 years before the Christian era. He was the first who turned the personal satyrs and scencenine verses, so long the admiration of the Romans, into the form of a proper dialogue and regular play. Though the character of a player, so valued and applauded in Greece, was reckoned vile and despicable among the Romans, Andronicus acted a part in his dramatical compositions, and engaged the attention of his audience, by repeating what he had laboured after the manner of the Greeks. Andronicus was the freedman of M. Livius Salinator, whose children he educated. His poetry was grown obsolete in the age

of Cicero, whose nicety and judgment would not even recommend the reading of it.

LIVONIA, a large province of the Russian empire, with the title of a duchy. It is bounded on the north by the gulph of Finland, on the west by that of Riga, on the south by Courland, and on the east, partly by Plescow, and partly by Novogorod. It is about 250 miles from north to south, and 150 from east to west. The land is so fertile in corn, that it is called the *granary of the north*; and would produce a great deal more, if it was not so full of lakes. The fish that abound here are salmon, carps, pikes, flat fish, and many others. In the forests there are wolves, bears, elks, rein-deer, stags, and hares. The domestic animals are very numerous; but the sheep bear very bad wool. Here are a great number of forests, which consist of birch-trees, pines, and oaks; and all the houses of the inhabitants are built with wood. The merchandizes which they send abroad are flax, hemp, honey, wax, leather skins, and potashes. The Swedes were formerly possessed of this province, but were obliged to abandon it to the Russians after the battle of Pultowa; and it was ceded to them by the peace of the North, concluded in 1722, which was confirmed by another treaty in 1742. It is divided into two provinces, viz. Letonia and Estonia; and two islands called *Oesel* and *Dagbo*, which are again subdivided into several districts.

LIVONICA-TERRA, a kind of fine bone used in the shops of Germany and Italy. It is found in Livonia, from whence it takes its name, and also in some other parts of the world. It is generally brought to us in little cakes, sealed with the impression of a church and an escutcheon, with two cross keys.

LIVRE, a French money of account, containing 20 sols. See *Monet-Table*.

LIXA, or LIXUS (anc. geog.) a town on the Atlantic near the river Lixus; made a Roman colony by Claudius Cæsar; famous in mythology for the palace of Anteus and his encounter with Hercules, (Pliny). Now *Larache*, sixty-five leagues to the south of the straits of Gibraltar.

LIXIVIOUS, an appellation given to salts obtained from burnt vegetables by pouring water on their ashes.

LIXIVIUM, in pharmacy, &c. a ley obtained by pouring some liquor upon the ashes of plants; which is more or less powerful, as it has imbibed the fixed salts contained in the ashes.

LIXNAW, a barony in the county of Kerry and province of Munster in Ireland, which gives title of Baron to the earls of Kerry; the village here of this name being their ancient seat, where the castle was erected. This seat stands agreeably on the river Brick, which is here cut into several pleasant canals, that adorn its plantations and gardens; the improvements are extensive, most of the viætes and avenues terminating by different buildings, seats, and farm-houses. The tide flows up to the gardens, whereby boats of a considerable burden may bring up goods to the bridge near the house: here are two stone-bridges over the Brick, the oldest of which was built by Nicholas the third baron Lixnaw, who was the first person that made causeways to this place, the land being naturally

LIZARD, in zoology. See **LACERTA**.

LIZARD, in geography, a cape or promontory of Cornwall, situated, according to the most common computation, in W. Long. 5. 47. N. Lat. 49. 50.

LLANDAFF. See **LANDAFF**.

LLOYD (Nicholas), a learned English writer in the 17th century, was born in Flintshire in England, and educated at Wadham college, Oxford. He was rector of Newington St Mary near Lambeth in Surry, till his death, which happened in 1680. His *Dictionarium Historicum* is a valuable work, to which Hoffman and Moreri are greatly indebted.

LLOYD (William), a most learned English writer and bishop, was born in Berkshire in England in 1627. He was educated under his father, rector of Sonning, and vicar of Tyle-hurst in Berkshire; then went to Oxford, and took orders. In 1660 he was made prebendary of Rippon; and in 1666 chaplain to the king. In 1667 he took the degree of doctor of divinity; in 1672 he was installed dean of Bangor; and in 1680 was consecrated bishop of St Asaph. He was one of the six bishops who, with archbishop Sancroft, were committed prisoners to the Tower of London, for subscribing a petition to the king against distributing and publishing his declaration for liberty of conscience. Soon after the revolution he was made almoner to king William and queen Mary: in 1692 he was translated to the bishopric of Litchfield and Coventry; and in 1699, to the see of Worcester, where he sat till his death, which happened in 1717, the 91st year of his age. Dr Burnet gives him an exalted character, and his works are highly esteemed.

LOACH, in ichthyology. See **COBITIS**.

LOAD, or **LODS**, in mining, a word used especially in the tin-mines, for any regular vein or course, whether metallic or not; but most commonly load means a metallic vein.

It is to be observed, that mines in general are veins or cavities within the earth, whose sides receding from or approaching to each other, make them of unequal breadths in different places, sometimes forming large spaces, which are called *bols*; these holes are filled like the rest with substances, which, whether metallic, or of any other nature, are called *loads*. When the substances forming these loads are reducible to metal, the loads are by the English miners said to be alive, otherwise they are termed dead loads.

In Cornwall and Devonshire the loads all hold their course from eastward to westward, tho' in other parts of England they frequently run from north to south. The miners report, that the sides of the load never bear in a perpendicular, but always overhang either to the north or south above. The mines seem to have been so many channels through which the waters pass within the earth; and like rivers they have their small branches opening into them in all directions: these are by the miners termed the feeders of the load. Most mines have streams of water running through them; and when they are found dry, it seems owing to the water having changed its course, which it seems sometimes to have been compelled to by the load's having filled up the course, and sometimes to have fallen into other more easy channels.

The load is frequently intercepted by the crossing of

a vein of earth or stone, or some other metalline substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. This transient load is, by the miners, termed a *floaking*; and the part of the load which is moved, is by them said to be *heaved*. This fracture or heave of a load, according to Mr Price, is produced by a subsidence of the strata from their primary positions, which he supposes to have been horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This heaving of the load would be an inexpressible loss to the miner, did not experience teach him, that as the loads always run on the sides of the hills, so the part heaved is always moved toward the descent of the hill; so that the miner, working toward the ascent of the hill, and meeting a floaking, considers himself as working in the heaved part; wherefore, cutting through the floaking, he works upon its back up the ascent of the hill, till he recovers the load, and *vice versa*.

LOAD is also used for nine dishes of ore, each dish being about half a hundred weight.

LOADSTONE. See **MAGNET**.

LOAMS, in natural history, are defined to be earths composed of dissimilar particles, stiff, dense, hard, and rough to the touch; not easily broke while moist, readily diffusible in water, and composed of sand and a tough viscid clay. Of these loams some are whitish and others brown and yellow.

LOAN, any thing given to another, on condition of return or payment.

Public Loans. See **FUNDS**, and **NATIONAL Debt**.

LOANDA, a province of the kingdom of Angola in Africa. It is an island about 15 miles in length, and three in breadth; remarkable chiefly for the capital of Angola situated upon it, in E. Long. 12. 25. S. Lat. 8. 45. This town was built by the Portuguese in 1578, under the direction of the first Portuguese governor in these parts. It is large, populous, and pleasantly seated on the declivity of a hill near the sea-coast, and facing the south-west. The island is supplied with fresh water from wells dug in it; and which are not sunk below the depth of three feet when they are filled with excellent water. It is remarkable, however, that the water of these wells continues good only during the time of high-tide; for, as that sinks, the water becomes more and more brackish, till at last it is quite salt, almost as much as the sea itself. On the coast of this island are fished the zimbis, or shells used in several parts of Africa instead of money; and with these shells, instead of coin, is carried on a great part of the traffic of this country.

LOANGO, a kingdom of Africa, extending itself about 180 geographical miles in length from south to north; that is, from cape St Catharine under the second degree of south latitude, to a small river called *Lovanda Louisa*, on the 5th degree of the same. From west to east it extends from Cape Negro on the coast of Ethiopia towards the *Buchumalean* mountains, so called on account of their vast quantity of ivory and great droves of elephants, about 300 miles. It is divided into four principal provinces, viz. those of Lovangiri, Loango-mongo, Chilongo, and Piri.

The inhabitants are very black, well-shaped, and of a mild-temper. The men wear long petticoats, from the waist downwards, and have round their waist a

Load

Loango.

Laango

||

Lobelia.

piece of cloth half an ell or a quarter broad, over which they wear the skin of a leopard, or some other wild beast, hanging before them like an apron. On their head they wear a cap made of grass, and quilted, with a feather a-top of it; and on their shoulder, or in their hand, they carry a buffalo's tail, to drive away the muskettoes. The womens petticoats are made only of straw, about an ell square, with which they cover their privities, but leave the greatest part of their thighs and buttocks bare: the rest of their body is quite bare, except that on their legs they wear little fringes of beads made of shells, and small bracelets of ivory on their arms. They anoint themselves with palm-oil, mixed with a kind of red wood reduced to powder.

This country abounds with poultry, oxen, cows, sheep, goats, elephants, tigers, leopards, civet-cats, and other animals; so that here are great quantities of elephants teeth, and fine furs, to be traded for.

The capital city, where the king resides, is called *Laango*, or *Banza-Laogeri*, and, in the language of the negroes, *Boarie*. This city is situated in South Lat. 4½ degrees, a league and a half from the seacoast. It is a pretty large city, shaded and adorned with bananas, palm, and other trees. The king, who resides in a large palace in the middle of it, has about 1500 concubines. If any of them is surprised in adultery, she and her paramour are instantly conveyed to the top of a very high hill, whence they are hurled down headlong from the steepest place.

Every man marries as many wives here as he pleases, who are obliged to get their husbands a livelihood, as is the practice all along the African coast inhabited by blacks. The women, therefore, cultivate the land, sow and reap, while the lazy husbands loiter away their time in idleness.

The king's revenue consists in elephants teeth, copper, and a kind of petticoats made of palm-tree leaves, and called *lavogus*: he has whole store-houses full of these *lavogus*; but his greatest riches consist in slaves of both sexes.

LOBBY, in architecture, is a small hall or waiting-room: it is also an entrance into a principal apartment, where there is a considerable space between that and a portico or vestibule, and the length or dimensions will not allow it to be considered as a vestibule or an antiroom. See ANTICHAMBER.

LOBE, in anatomy, any fleshy protuberant part, as the lobes of the lungs, the lobes of the ears, &c.

LOBELIA, CARDINAL-FLOWER: A genus of the monogamia order, belonging to the syngenesia class of plants; and in the natural method ranking under the 29th order, *Campnaceae*. The calyx is quinquefid; the corolla monopetalous, and irregular; the capsule inferior, bilocular, or trilocular. There is a great number of species, but only four of them are cultivated in our gardens; two of which are hardy herbaceous plants for the open ground, and two shrubby plants for the stove. They are all fibrous rooted perennials, rising with erect stalks from two to five or six feet high, ornamented with oblong, oval, spear-shaped, simple leaves; and spikes of beautiful monopetalous, somewhat ringent, five-parted flowers, of scarlet, blue, and violet colours. They are easily propagated by seeds, offsets, and cuttings of their stalks. The tender kinds require

the common treatment of other exotics. They are natives of America; from which their seeds must be procured.

The root of a species called the *siphilitica* is an article of the materia medica. This species grows in moist places in Virginia, and bears our winters. It is perennial, has an erect stalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North American Indians as a specific in the venereal disease. The form is that of decoction; the dose of which is ordered to be gradually increased till it bring on very considerable purging, then to be intermitted for a little, and again used in a more moderate degree till the cure be completed. The ulcers are also washed with the decoction, and the Indians are said to sprinkle them with the powder of the inner bark of the spruce tree. The same strictness of regimen is ordered as during a salivation or mercurial course. The benefit to be derived from this article has not, as far as we know, been confirmed either in Britain or by the practitioners in Virginia: for there, as well as in this country, recourse is almost universally had to the use of mercury; and it is probably from this reason that the London college have not received it into their list. It, however, seems to be an article which, in some cases at least, deserves a trial.

LOBETUM, anciently a town of the Hither Spain: said to have been built by the Libyan Hercules, (Pliny.) Now *Albarazin*, a town of Arragon on the confines of New Castile, on the river Guadalquivir. E. Long. 2. N. Lat. 40. 40.

LOBINEAU (Guy Alexis), a Benedictine monk, born at Renne in 1666, spent his whole life in the study of history, and the writing of several works; the principal of which are, *The history of Brittany*, 2 vols folio; and *A continuation of Felibien's history of Paris*, 9 vols folio. He died in 1727.

LOBO (Rodriguez Francis), a celebrated Portuguese poet, was born at Leiria, a small town of Estramadura. He wrote an heroic poem, some eclogues, and a piece intitled *Euphrosyne*, which is the favourite comedy of the Portuguese. His works were collected and printed together in Portuguese in 1721, in folio. He flourished about 1610.

LONO (Jerome), a famous Portuguese Jesuit, born at Lisbon, went into Ethiopia, and dwelt there for a long time. At his return he was made rector of the college of Coimbra, where he died in 1678. He wrote *An historical account of Abyssinia*, which is by some esteemed a very accurate performance.

LOBSTER, in zoology, a species of cancer. See CANCER.

LOCAL, in law, something fixed to the freehold, or tied to a certain place: thus, real actions are local, since they must be brought in the country where they lie; and local customs are those peculiar to certain countries and places.

LOCAL Medicines, those destined to act upon particular parts; as fomentations, epithems, vesicatories, &c.

LOCARNO, a town of Switzerland, capital of a bailiwick of the same name, seated at the north end

Locatellus of the lake Maggiore, near the river Magie. It carries on a great trade; and the country abounds in pastures, wine, and fruits. E. Long. 8. 41. N. Lat. 46. 6.

LOCATELLUS's BALSAM. See PHARMACY-Index.

LOCHABER, a district of the shire of Inverness in Scotland. It is bounded by Moydart on the west, Glengary on the north, Badenoch on the east, and Lorn on the south. It derives its name from the lake or loch Aber; and extends about 20 miles from east to west, and 30 from north to south. The country is barren, bleak, mountainous, and rugged. In one of the most barren parts of this country, near the mouth of the river Aber, in the centre between the West and North Highlands, stands Fort-William, with the town of Maryburgh, built upon a navigable arm of the sea, not far from the foot of a very high mountain, called *Benevis*. The town, designed as a sutler for the garison, was erected into a borough; and the fort itself was designed as a check upon the clan Cameron, who had been guilty of depredations and other irregularities. It is inhabited mostly by the Macdonalds, Camerons, and Mackintoshes; who are not the most civilized people in Scotland, though their chiefs are generally persons of education, honour, and hospitality. Macdonald of Glengary, descended in a straight line from Donald of the Isles, possessed a feat or castle in this district, which was burnt to the ground; and destroyed in the year 1715, in consequence of his declaring for the Pretender. The elegant house and gardens belonging to Cameron of Lochiel underwent the same fate, for the same reason, after the extinction of the rebellion in the year 1746. The cadets of these families, which have formed a kind of inferior gentry, are lazy, indigent, and uncleanly; proud, ferocious, and vindictive. The common people, though celebrated for their bravery, fidelity, and attachment to their chiefs, are counted very savage, and much addicted to rapine. They speak the Erse language, and conform to the customs we have described as peculiar to the Highlanders. They pay very little attention to any sort of commerce but that which consists in the sale of their black cattle, and lead a sort of vagrant life among the hills; hunting, fowling, and fishing, as the seasons permit, and as their occasions require. They delight in arms, which they learn to handle from their infancy; submit patiently to discipline in the character of soldiers; and never fail to signalize themselves in the field by their sobriety, as well as their valour. While they remain in their own country, nothing can be more penurious, mean, sordid, and uncomfortable, than the way of life to which these poor people are inured, whether we consider their dress, diet, or lodging. In point of provision, they are so impoverished or ill supplied, that, before the winter is over, whole families are in danger of starving. In this emergency, they bleed their miserable cattle, already reduced to skin and bone, and eat the blood boiled with oatmeal. This evacuation, added to their former weakness, enfeebles the cows to such a degree, that when they lie down they cannot rise again without assistance.

LOCHIA, in midwifery, a flux from the uterus consequent to delivery. See MIDWIFERY.

LOCK, a well-known instrument used for fastening doors, chests, &c. generally opened by a key.

The lock is reckoned the master-piece in smithery; a great deal of art and delicacy being required in contriving and varying the wards, springs, bolts, &c. and adjusting them to the places where they are to be used, and to the various occasions of using them.

From the various structure of locks, accommodated to their different intentions, they acquire various names. Those placed on outer-doors are called *stock-locks*; those on chamber-doors, *spring-locks*; those on trunks, *trunk-locks*, *pair-locks*, &c.

Of these the spring-lock is the most considerable, both for its frequency and the curiosity of its structure. Its principal parts are, the main-plate, the cover-plate, and the pin-hole: to the main-plate belong the key-hole, top-hook, cross-wards, bolt-toe or bolt-knob, drawback-spring tumbler, pin of the tumbler, and the staples; to the cover-plate belong the pin, main-ward, cross-ward, step-ward or diap-ward; to the pin-hole belong the hook-ward, main cross-ward, shank, the pot or bread, bow-ward, and bit.

As on the proper construction of locks the security of the most valuable kinds of property almost entirely depends, and as numberless devices are continually fallen upon to elude the utmost efforts of mechanical invention in this respect, it thence becomes an object of no small importance to invent a lock which it should be impossible to open except by its proper key. A treatise upon this subject has been published by Mr Joseph Brama; who is confident that he has brought the matter to the requisite perfection, and that every one may rest assured of the security of his property when under the protection of a lock of his invention. He begins with observing, that the principle on which all locks depend, is the application of a lever to an interior bolt, by means of a communication from without; so that, by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general therefore depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of *wards*, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lock-maker to open it without the key, and thus to elude the labour of the other.

"Locks (says our author) have been constructed, and are at present most used and held in great esteem, from which the picklock is excluded: but the admission of false keys is an imperfection for which no locksmith has ever found a corrective; nor can this imperfection be remedied whilst the protection of the bolt is wholly confined to *fixed wards*." This position is proved by a remark, that the wards, let them be as intricate as we please, must all be expressed on what is called the *bit* or *web* of the key: and therefore, when all the varieties that can be expressed on this bit or web have been run through, every succeeding lock must be the counterpart of some other; and consequently the same.

same key which opens one will open the other also. This is evident from the locks usually put upon drawers; and which, though they should be made to refit the picklock, are still liable to be opened by ten thousand other keys besides that appropriated to each of them. But though the variety of wards could be augmented even to infinity, still there could be no security against false keys; for as every one of the wards must be expressed on the web of the key, if another key with a web quite plain be made to fit the key-hole exactly, we have only to cover it over with some colouring substance upon which the wards may make an impression; after which, it is easy to cut out the web in a proper manner for admitting them, when the lock will be as easily opened by the false as by the true key.

The first person, according to our author, who had any claim to merit in the branch of lock-making, is Mr Baron; whose lock he acknowledges to be by far more perfect and secure than any that ever appeared before; though he still considers it as unfit for giving that absolute security which is to be wished for. His improvement consisted in the proper application of what are called *grapples*. "These (says Mr Braham) are a kind of grapple; by which the bolt is confined, as well in its active as in its passive station, and rendered immoveable till set at liberty by the key. One of these instruments is commonly introduced into all locks that are of any use or value; it is lodged behind the bolt, and is governed by a spring which acts upon the tumbler as the tumbler acts upon the bolt: The application therefore of any force to the tumbler, which is superior to the force of the spring, will cause it to quit its hold, and set the bolt at liberty." In the common method of applying these machines, however, it matters nothing how far the tumbler is lifted above the point at which it ceases to control the bolt; but it is otherwise in those of Mr Baron's construction. The action of his tumblers is circumscribed by a certain space cut in the centre of the bolt, of dimensions sufficient only to answer the purpose intended. The space in which the tumbler moves is an oblong square; and is not only furnished with niches on the under side into which the hooks of the tumblers are forced by the spring as in other locks, but is provided with correspondent niches on the other side, into which the hooks are driven, if any greater force be applied to the tumblers than what is just sufficient to disengage them from the bolt. Hence it becomes absolutely necessary, in the making of a false key, to construct it in such a manner, that it may with the greatest exactness give the requisite degree of pressure, and no more.

Mr Braham allows that this is a very great improvement, but objects that it is still possible to frame a key which will open it as well as its own; nor will the addition of any number of tumblers preclude the possibility of opening it. "By giving (says he) an uniform motion to the tumblers, and presenting them with a face which exactly tallies with the key, they still partake, in a very great degree, of the nature of *fixed wards*; and the security of his lock is thereby rendered in a proportionable degree defective. Thus, suppose the false key to have passed the wards, and to be in contact with the most prominent of the tumblers, the impression, which the slightest touch will leave on the key, will direct the application of the file till

sufficient space is prepared to give it a free passage. The key will then bear upon a more remote tumbler; which difficulty being in like manner got over, the lock will be as easily opened by the false as by the true key."

This seemingly insuperable objection to the perfection of lock-making, however, our author removes with the greatest ease imaginable, by causing the tumblers which project unequally to present a *plane surface*: whence they would require a separate and unequal motion to disengage them; of consequence no distinct impression could be made by them upon the plane surface of the web that would give any idea of their positions with regard to one another, and the construction of a false key would be altogether impossible.

But though the principal difficulty with regard to Mr Baron's lock be now overcome, others still occur, *viz.* the difficulty of making locks which are constructed with tumblers sufficiently durable. The tumblers themselves, he observes, must be but slightly made; and being exposed to perpetual friction by the key and their own proper motion, they must soon decay; and the keys of Mr Baron's locks, he also observes, are much less durable than those of any other locks he ever saw.

With regard to the lock which Mr Braham presents to the public as absolutely perfect, he informs us, that the idea of constructing it was first suggested by the alarming increase of house-robberies, which may reasonably be supposed to be perpetrated in a great measure by perfidious servants, or accomplished by their connivance. Thus it is evident, that the locks which might exclude ordinary house-breakers could be no security against faithless servants, who having constant access to the locks, might easily get false keys fabricated at their leisure. In considering the subject, our author was convinced, that his hope of success depended entirely upon his using means as dissimilar as possible to those by which the old locks were constructed; as these, however varied, had been found insufficient for the purpose. "As nothing (says he) can be more opposite in principle to *fixed wards* than a lock which derives its properties from the *motion* of all its parts, I determined that the construction of such a lock should be the subject of my experiment." In the prosecution of this experiment he had the satisfaction to find, that the least perfect of all his models fully ascertained the truth and certainty of his principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage, which (in a lock *simply* constructed) would admit the key, might give admission likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here assigned to a lever, which cannot approach the bolt till every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the absolute impossibility of effecting it otherwise than with the proper key, are the points to be ascertained; and this our author does in the following manner.

Fig. 1. Shows Mr Braham's first attempt to construct a lock upon this principle: which, to his surprise, turned out complete and perfect. A represents a common axis on which the six levers, crossing the face

Lock.

face of the lock, are united as on a joint. Each of these rests upon a separate spring sufficiently strong to bear its weight; or, if depressed by a superior force, to restore it to its proper position when that force is removed. B represents a frame through which the levers pass by separate grooves, exactly fitted to their width, but of sufficient depth to allow them a free motion in a perpendicular direction. The part which projects from the opposite side of the joint A, and is inserted in the bolt C, is a lever to which two offices are assigned; one to keep the bolt in a fixed position, in the absence of the key; the other, to give it its proper motion upon the application of the key. D is a circular platform turning upon a centre. On this the joint or carriage of the levers, and the springs on which they rest, are fixed; and the motion of this platform impels the bolt, in either direction, by means of the lever which is projected from the joint A. The inviolable restraint upon this lock, by which means it is subjected only to the action of the key, is lodged in the part E, which is a thin plate, bearing at each extremity on a block, and having of course a vacant space beneath, equal in height to the thickness of the blocks on which it rests. By this plate the motion of the machine is checked or guided in the following manner: On the edge of the plate which faces the movement there are six notches, which receive the ends of the levers projecting beyond the frame B; and while they are confined in this manner, the motion of the machine is so totally suspended as to defy every power of art to overcome.

To understand in what manner the proper key of this lock overcomes these obstacles, it must be observed, that each lever has a notch on its extremity, and that those notches are disposed as irregularly as possible. To give the machine a capacity of motion, these notches must be brought parallel to each other, and by a distinct but unequal pressure upon the levers, be formed into a groove in a direct line with the edge of the plate E, which the notches are exactly fitted to receive. The least motion of the machine, while the levers are in this position, will introduce the edge of the plate into the groove; which, controuling the power of the springs, will give liberty to the levers to move in an horizontal direction as far as the space between the blocks which support the plate E will admit, and which is sufficient to give the machine a power of acting on the bolt. The impossibility of thus bringing the notches on the points of the levers into a direct line, so as to tally with the edge of the plate E by any other means than the motion and impulse of the key, is that which constitutes the principal excellency of this lock.

The key (fig. 2.) exhibits six different surfaces, against which the levers are progressively admitted in the operation of opening the lock: the irregularity of these surfaces shows the unequal and distinct degree of pressure which each lever requires to bring them to their proper bearings, in order to put the machine in motion. Hence it appears, that unless the various heights of the surfaces expressed on the bit of the key are exactly proportioned to the several distances necessary to bring the notches into a straight line with each other, they must remain immovable; "and (says our author) as one stroke of a file is sufficient to cause

such a disproportion as will prove an unfurmountable impediment to their motion, I may safely assert, that it is not in art to produce a key or other instrument, by which a lock, constructed upon this principle, can be opened."

On this principle it would even be a matter of great difficulty for any workman, however skilful, to construct a key for the lock when open to his inspection: "for the levers being raised, by the subjacent springs, to an equal height in the frame B, present a plane surface; and consequently convey no direction that can be of any use in forming a tally to the irregular surface which they present when acting in subjection to the key. Unless therefore we can contrive a method to bring the notches on the points of the levers in a direct line with each other, and to retain them in that position till an exact impression of the irregular surface, which the levers will then exhibit, can be taken; the workman will be unable to fit a key to the lock, or to move the bolt. This process must be rendered extremely troublesome by means of the springs; and if such difficulties occur, even when the lock is open to the inspection of a skilful workman, much more must we suppose it out of the power of one who has not access to the internal parts to make a false key to a lock of this kind.

These difficulties render it necessary in making locks of this kind not to fit the key to the lock, as is usual in other locks, but to fit the lock to the key. In this kind of lock, therefore, the key must be made first; and the inequalities upon the surface of the bit worked as chance or fancy may direct, without any reference to the lock. The key being thus completed, and applied to the surface of the levers, will, by a gentle pressure, force them to unequal distances from their common station in the frame B, and sink their points to unequal depths into the space beneath the plate E. While the levers are in this position, the edge of the plate E will mark the precise point at which the notch on each lever must be expressed. The notches being cut by this direction, the irregularity which appears when the levers resume their station in the frame B, and the inequality of the recesses on the bit of the key, will appear as a seal and its corresponding impression.

The following is a lock contrived upon the same principle, but more curious; and, in our author's opinion, more extensively useful. Fig. 3. represents a circular block of metal divided from the centre into eight compartments, each containing a cell which forms a passage through the block, as is represented by the small circles described on the flat surface A. In each of these cells two grooves are cut at opposite points, which open a communication with the centre at one point, and with the spherical surface of the block or barrel at the other. The small circle, which marks the centre of the flat surface A, is the key-hole, which likewise forms a passage through the barrel in a parallel line with the cells which surround it. This figure represents the frame in which the active parts of the lock are deposited.

Fig. 4. shows a spiral spring lodged in the bottom of each cell, and occupying one half of the space, the other being filled with a slider resting upon the spring, and represented by fig. 5. the office of these sliders ex-

P actively

Look.

ally corresponding with that of the levers in the lock already described. Thus, when lodged in their respective cells, they are sustained, like the levers, by the elasticity of the springs upon which they rest, till a superior power be applied; and they are again restored to their stations by the reaction of the springs when the weight is removed. The side B of each slider is projected beyond the circular surface, as represented fig. 6. in a manner similar to the projection of the levers in the former lock beyond the curved frame in which they move. The point C is projected through the interior groove into the space which forms the centre or key-hole, expressed on the flat surface A.

Fig. 7. represents the key. When this is applied, it must of course encounter these interior projections; and when pressed forward, the indented spaces on its point being unequal, will force the sliders to unequal distances from their bearers; bringing the notches expressed on their exterior projections in a direct line with each other, in a manner similar to that by which the effect is produced upon the levers in the former lock. When the key is withdrawn, and the sliders resume their stations by the pressure of the springs, the disposition of the notches must be irregular in the same proportion that the indentations on the point of the key are unequal; and they must necessarily fall again into a straight line when acted upon by the key.

Fig. 6. shows the barrel completely fitted for action. Its interior end is capped with a plate, which unites its compartments, and confines the springs and sliders within the cells to which they belong. From that plate proceeds the point A, which represents the lever by which the bolt is projected or withdrawn, according to the direction in which the machine performs its revolution.

Fig. 8. shows the flat surface of a thin plate, corresponding in its office with the part C of the former lock. The space cut in its centre is exactly fitted to the spherical surface of the barrel; the circle describing its circumference, and the notches cut on its edge, coinciding with the projections of the sliders. The barrel, when encircled with this plate at the middle of its spherical surface, has its motion totally suspended till the notches on the projections of the sliders are forced, by the pressure of the key, into a line with each other: a groove being thus formed on the spherical surface of the barrel parallel to, and coinciding with, the edge of the plate, the machine is at liberty to perform a revolution in any direction, but returns to its confined state when the key is withdrawn.

The parts of the movement being thus united, the interior end of the barrel is deposited in a bed represented fig. 9. To this it is fastened at the angles of the plate represented fig. 8. by which the barrel is encircled. The station of the bolt is at A; the lever which acts upon it being projected on the other side. Fig. 10. is a cap or maul which covers the face of the movement, and completes the lock.

On this lock our author observes, that it is excellent for street-doors: "for no method of robbery (says he) is more practised, than gaining admittance into houses by those keys, which, as is well known, may be procured at the old iron shops to fit almost any lock in use. Such robberies are generally committed where the servants are allowed to take the key with them

when sent on errands, it being impracticable while the key is fixed in the lock. The variations, by which the production of correspondent keys is avoided, have two sources: the one arising from the changes that may be made in the disposition of the levers; the other, from the number of points contained on the projected surface of each lever; by which the position of its notch may, in the smallest degree, be varied.

"The variations, producible in the dispositions of six figures only, are 720: these, being progressively multiplied by additional figures, will increase by astonishing degrees; and eventually show, that a lock containing twelve levers will admit of 479,001,500 changes; which, with the addition of another lever, will increase to 6,229,019,500. These being again multiplied by the number of changes which the projected surface of the levers will admit in the disposition of the notches, their amount will exceed numeration, and may therefore be properly said to be infinite. The slightest inspection will at once show, that their construction precludes all possibility of obtaining an impression of their internal parts, which is necessary for the fabrication of a false key; for it will be easily seen, that the positions into which the levers are forced by the pressure of the key in opening the lock, can no more be ascertained when the key is withdrawn, than the seal can be copied from its impression on a fluid, or the course of a ship be discovered by tracing it on the surface of the waves. But inviolable security is not the only excellence they possess: the simplicity of their principle gives them likewise a great advantage over locks that are more complicated, in point of duration; for their essential parts being subject to no friction, nor exposed to any possible accident from without, they will be less affected by use, and less liable to stand in need of repair."

Lock, or *weir*, in inland navigations, the general name for all those works of wood or stone made to confine and raise the water of a river: the banks also which are made to divert the course of a river, are called by these names in some places. But the term *lock* is more particularly appropriated to express a kind of canal inclosed between two gates; the upper called by workmen the sluice-gate, and the lower called the flood-gate. These serve in artificial navigations to confine the water, and render the passage of boats easy in passing up and down the stream. See CANAL.

LOCKE (John), a most eminent English philosopher and writer in the latter end of the 17th century, was son of Mr John Locke of Pensford in Somersetshire, and born at Wrington near Bristol in 1632. He was sent to Christ-church in Oxford; but was highly dissatisfied with the common course of studies then pursued in the university, where nothing was taught but the Aristotelian philosophy; and had a great aversion to the disputes of the schools then in use. The first books which gave him a relish for philosophy, were the writings of Des Cartes: for though he did not always approve of his notions, yet he thought he wrote with great perspicuity. He applied himself with vigour to his studies, particularly to physics, in which he gained a considerable knowledge, though he never practised it. In 1694, he went to Germany as secretary to Sir William Swan, envoy from the English court to the elector of Brandenburg and some other

Lock.

Locke.

other German princes. In less than a year, he returned to England; where, among other studies, he applied himself to that of natural philosophy, as appears from a register of the changes of the air, which he kept at Oxford from June 24. 1666, to March 28. 1667. There he became acquainted with the lord Ashly, afterwards earl of Shaftesbury, who introduced him into the conversation of some of the most eminent persons of that time. In 1670, he began to form the plan of his *Essay on Human Understanding*; but his employments and avocations prevented him from finishing it then. About this time he became a member of the Royal Society. In 1672, his patron, now earl of Shaftesbury, and lord chancellor of England, appointed him secretary of the presentations, which place he held till the earl resigned the great seal. In 1673, he was made secretary to a commission of trade, worth 500*l.* a-year; but that commission was dissolved in 1674. The earl of Shaftesbury being restored to favour, and made president of the council in 1679, sent for Mr Locke to London: but that nobleman did not continue long in his post, being sent prisoner to the tower; and after his discharge retired to Holland in 1682.

Mr Locke followed his patron thither. He had not been absent from England a year, when he was accused at court of having written certain tracts against the government, which were afterward discovered to be written by another person; and in November 1684, he was deprived of his place of student in Christ-church. In 1685, the English envoy at the Hague demanded him and 83 other persons to be delivered up by the States General: upon which he lay concealed till the year following; and during this time formed a weekly assembly with Mr Limborch, Mr Le Clerc, and other learned men at Amsterdam. In 1689 he returned to England in the fleet which conveyed the prince of Orange; and endeavoured to procure his restoration to his place of student of Christ-church, that it might appear from thence that he had been unjustly deprived of it: but when he found the college would admit him only as a supernumerary student, he desisted from his claim.

Being esteemed a sufferer for revolution-principles, he might easily have obtained a more profitable post; but he contented himself with that of commissioner of appeals, worth 200*l.* a year, which was procured for him by the Lord Mordaunt, afterwards earl of Monmouth, and next of Peterborough. About the same time he was offered to go abroad in a public character; and it was left to his choice, whether he would be envoy at the court of the emperor, that of the elector of Brandenburg, or any other where he thought the air most suitable to him: but he waved all these, on account of the infirm state of his health; which disposed him gladly to accept another offer that was made by Sir Francis Mafham and his lady, of an apartment in their country-seat at Oates in Essex, about 25 miles from London.

This place proved so agreeable to him in every respect, that it is no wonder he spent the greatest part of the remainder of his life at it. The air restored him almost to a miracle, in a few hours after his return at any time from the town, quite spent and unable to support himself. Besides this happiness here, he

found in lady Mafham a friend and companion exactly to his heart's wish; a lady of a contemplative and studious complexion, and particularly inured, from her infancy, to deep and refined speculations in theology, metaphysics, and morality. In this family Mr Locke lived with as much ease as if the whole house had been his own; and he had the additional satisfaction of seeing this lady breed up her only son exactly upon the plan which he had laid down for the best method of education; the success of which was such as seemed to give a sanction to his judgment in the choice of that method. In effect, it is to the advantage of this situation that he derived so much strength as to continue exerting those talents which the earl of Shaftesbury had observed to be in him for political subjects. Hence we find him writing in defence of the revolution in one piece; and considering the great national concern at that time, the ill state of the silver coin, and proposing remedies for it, in others. Hence he was made a commissioner of trade and plantations in 1695, which engaged him in the immediate business of the state; and with regard to the church, he published a treatise the same year, to promote the scheme which king William had much at heart, of a comprehension with the dissenters. This, however, drew him into one controversy; which was scarcely ended, when he entered into another in defence of his essay, which held till 1698: soon after which the asthma, his constitutional disorder, increasing with his years, began to subdue him; and he became so infirm, that in 1700 he resigned his seat at the board of trade, because he could no longer bear the air of London sufficient for a regular attendance upon it. After this resignation he continued altogether at Oates; in which retirement he employed the remaining last years of his life entirely in the study of the holy Scriptures.

He died in 1704, aged 73. His writings will immortalize his name. The earl of Shaftesbury, author of the *Characteristicks*, though in one place he speaks of Mr Locke's philosophy with severity; yet observes, concerning his *Essay on the Human Understanding*, in general, "that it may qualify men as well for business and the world, as for the sciences and the universality." Whoever is acquainted with the barbarous state of the philosophy of the human mind, when Mr Locke undertook to pave the way to a clear notion of knowledge, and the proper methods of pursuing and advancing it, will be surprized at this great man's abilities; and plainly discover how much we are beholden to him for any considerable improvements that have been made since. His *Discourses on Government*, *Letters on Toleration*, and his *Commentaries on some of St Paul's Epistles*, are justly held in the highest esteem.

LOCKED JAW. See (the *Index* subjoined to) **MEDICINE.**

LOCKMAN, an officer in the Isle of Man, who executes the orders of government, much like our undersheriff.

LOCKMAN, an eastern philosopher. See **LOCKMAN.**

LOCLE, a small town in a district of the same name in Switzerland, adjacent to Neuchâtel and Valengin, and united with another named *La Glause de Fond*. Both these districts occupy some valleys formed by the mountains of Jura; the greatest part of

Locle,
Locri.

which not many years ago was one continued forest, though now converted into fine pasture-ground fitted with flourishing villages. The increase of population in these districts is particularly evident from the following circumstance, *viz.* that formerly the produce of the country was more than sufficient to serve the inhabitants; but now, though considerably better cultivated, it scarce furnishes an eighth part of the necessary consumption. This great increase of numbers is owing to the early marriages of the inhabitants; to the liberty allowed to every stranger, who brings a certificate of his good behaviour, to settle in the district; to follow any trade without restriction, and without an apprenticeship; and to the want of taxes, and an unbounded freedom of commerce. The industry and genius of the people in these districts is very surprising. They carry on an extensive commerce in lace, stockings, cutlery, and other merchandise of their own manufacture; and particularly excel in every branch of watch and clock making. They make all the utensils necessary in these arts, and have invented several new ones. There are also in these districts painters, gilders, enamellers, engravers, and other artists necessary for completing the business of watch making; by which means that business is carried on to so great an extent, that 40,000 watches are computed to be annually made. Besides these arts already mentioned, the people are extremely ingenious in other branches of mechanics, and have invented several astronomical and mathematical instruments. One of the most eminent in this way is Jaquet Droz, now at Paris; and whose son exhibited several surprising automatical figures in England. One of these played upon a harpichord; another drew landscapes; and a third copied any word presented to it, or wrote down whatever was dictated by any of the company.

The inhabitants of these districts are very courteous to strangers who visit them: they are in general well informed in several branches of knowledge; and as they commonly employ their leisure hours in reading, they have circulating libraries in many of their villages. Their houses are plastered, white washed, well built, and commodious, though small; being besides furnished with a degree of neatness and even elegance peculiarly striking in these sequestered mountains. "Such perfect ease and plenty (says Mr Coxe) reigns throughout these mountains, that I scarcely saw one object of poverty: the natural effects of industry under a mild and equitable government."

LOCRI, or *Locri Epizephyrii*, (anc. geog.), a town of the Brutii, on the Ionian sea: a colony of the Locri Ozolæ (Strabo); rather of the Epicnemidii (Virgil), who calls it *Naryeti Locri*, from Naryx a town of the Locri Epicnemidii. The epithet *Epizephyrii* is from its situation near the promontory Zephyrium (Strabo); *Locri* and *Locrenses*, the people. They are said to be the first who used a code or body of written laws, compiled by Zalcucus from the laws of the Cretans, Lacedæmonians, and the Areopagitæ, adding an express penalty to each law, which was before discretionary, at the option of the judge (Strabo). Adultery was punished with the loss of both eyes. His own son being convicted of this crime; to maintain at the same time the authority of the law, and to pay some regard to the intercession of the people in favour of his son,

Zalcucus suffered the loss of an eye, his son losing another (Ælian, Val. Maximus.)

LOCRIIS, the district or territory of Locri in the Brutii in Italy.

LOCRIIS, a country of Achaia in Greece; twofold, and divided by mount Parnassus. The Hither was occupied by the Locri Ozolæ, called also *Zephyrii*, or Western, contained between Ætolia and Phocis, beginning at Naupactum, and running in a narrow slip of land, scarce 200 stadia, along the sea to the borders of the Phœociens. The Farther Locriis lay beyond Parnassus, running out towards Thermopylæ, and reaching to the Euripus of Eubœa; occupied by the Locri Opuntii, who dwelt on the Eubœan sea; and the Epicnemidii, who occupied mount Cnemis (Strabo); and these two were the Eastern Locri.

LOCUS GEOMETRICUS, denotes a line by which a local or indeterminate problem is solved.

A *locus* is a line, any point of which may equally solve an indeterminate problem. Thus if a right line suffice for the construction of the equation, it is called *locus ad rectum*; if a circle, *locus ad circulum*; if a parabola, *locus ad parabolam*; if an ellipsis, *locus ad ellipsin*: and so of the rest of the conic sections.

LOCULAMENTA, and LOCULI, in botany; cells or pockets: The internal divisions of a capsule, or other dry seed-vessel, so termed.—These cells contain or inclose the seeds; and are different in number in different plants.

The term LOCULUS is also sometimes used to express the minute divisions in some species of *antheræ*, which contain the fine impalpable powder supposed by the sexualists to be the principal agent in the generation of plants.

LOCUST, in zoology. See GRYLLUS.

LOCUST-Eaters. See ACRIDOPHAGI.

American LOCUST, or Frog-hopper. See CICADA.

LOCUST-Tree. See HYMENÆA and GLEDITSIA.

LOCUTIUS, in mythology, the god of speech among the Romans, called by Livy *Avus Locutius*.

LOCUTORIUM. The monks and other religious in monasteries, after they had dined in their common hall, had a withdrawing-room, where they met and talked together among themselves, which room, for that sociable use and conversation, they called *locutorium*, a *loquendo*; as we call such a place in our houses parlour, from the French *parler*; and they had another room, which was called *locutorium forinsecum*, where they might talk with laymen.

LODGMET, in military affairs, a work made by the besiegers in some part of a fortification (after the besieged have been driven out), to maintain it, and be covered from the enemy's fire.—When a lodgement is to be made on the glacis, covert-way, or in a breach, there must be a great provision made of fascines, sand-bags, gabions, wool-packs, &c. in the trenches; and during the action, the pioneers, under the direction of an engineer, with fascines, sand-bags, &c. should be making the lodgment, in order to form a covering, while the grenadiers are storming the covert-way.

LODE, in mining. See LOAD.

LOG, in the Jewish antiquities, a measure which held a quarter of a cab, and consequently five-sixths of a pint. There is mention of a log, 2 Kings vi. 25.

under the name of a *fourth part of a cab*. But in Leviticus the word *log* is often met with, and signifies that measure of oil which lepers were to offer at the temple after they were cured of their disease. Dr Arbuthnot says, that the *log* was a measure of liquids, the seventy-second part of the bath or ephah, and twelfth part of the hin, according to all the accounts of the Jewish writers.

Plate
CCLXXII
fig. 3.

Log, a sea term, signifying a small piece of timber *a*, of a triangular, fectoral, or quadrantal figure, on board a ship, generally about a quarter of an inch thick, and five or six inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular side, so as to swim perpendicularly in the water, with about two thirds immersed under the surface.

Log-Line, a little cord, or line, about a hundred and fifty fathoms long, fastened to the log by means of two legs *ab* (fig. 4.), one of which passes through a hole at the corner, and is knotted on the opposite side, while the other leg is attached to the web by a pin fixed into another hole, so as to draw out occasionally. By these legs the log is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpose in the gallery of the ship.

This line, from the distance of about ten, twelve, or fifteen fathoms off the log, has certain knots or divisions, which ought to be at least fifty feet from each other; though it was the common practice at sea not to have them above forty-two feet asunder.

The length of each knot ought to be the same part of a sea-mile as half a minute is of an hour; and admitting the measurement of Mr Norwood, who makes a degree on a great circle of the earth to contain 367,200 English feet, or about 60½ English statute miles, and, therefore, $\frac{1}{60}$ th part of it, or a nautical mile, will be 6120 feet; $\frac{1}{12}$ th of 6120, or 51 feet, should be the length of each knot. But because it is safer to have the reckoning rather before the ship than after it, therefore fifty feet may be taken as the proper length of each knot. The knots are sometimes made to consist only of forty-two feet each, even in the present practice; and this method of dividing the log-line was founded on the supposition that sixty miles, each of 5000 English feet, made a degree; for $\frac{1}{60}$ of 5000 is 83⅓, or, in round numbers, 82 feet. Mariners, rather than quit the old way, though known to be erroneous, use glasses for half minute ones, that run but 24 or 25 seconds. They have also used a line of 45 feet to 30 seconds, or a glass of 28 seconds to 42 feet. When this is the case, the distance between the knots should be corrected by the following proportion: as 30 is to 50; so is the number of seconds of the glass to the distance between the knots upon the line. The heat or moisture of the weather has often a considerable effect upon the glass, so as to make it run slower or faster; it should, therefore, be frequently tried by the pendulum in the following manner. On a round nail hang a string that has a musket-ball fixed to one end, carefully measuring between the centre of the ball and the string's loop over the peg 39½ inches, being the length of a second pendulum; then swing it, and count one for every time it passes under the peg, beginning at the second time it passes; and the number of swings made during the time

the glass is running out shows the seconds it contains. The line also is liable to relax and shrink, and should therefore be occasionally measured.

The use of the log and line is to keep account and make an estimate of the ship's way or distance run; which is done by observing the length of line unwound in half a minute's time, told by a half-minute glass; for so many knots as run out in that time, so many miles the ship sails in an hour. Thus, if there be four knots veered out in half a minute, the ship is computed to run four miles an hour.

The author of this device for measuring the ship's way is not known; and no mention of it occurs till the year 1607, in an East-India voyage published by Purchas; but from that time its name occurs in other voyages among his collections; and henceforward it became famous, being taken notice of both by our own authors and by foreigners; as by Gunter in 1623; Snellius in 1624; Metius in 1631; Oughtred in 1633; Herigone in 1634; Saltonstall in 1636; Norwood in 1637; Pournier in 1643; and almost by all the succeeding writers on navigation of every country.

To *Heave the Log*, as they call it, they throw it into the water on the lee-side, letting it run till it comes without the eddy of the ship's wake; then one, holding a half-minute glass, turns it up just as the first knot, or the mark from which the knots begin to be reckoned, turns off the reel (fig. 2.) or passes over the stern. As soon as the glass is out, the reel is stopped, and the knots run off are told, and their parts estimated.

It is usual to heave the log once every hour in ships of war and East-India men, and in all other vessels once in two hours; and if at any time of the watch the wind has increased or abated in the intervals, so as to affect the ship's velocity, the officer generally makes a suitable allowance for it at the close of the watch.

The log is a very precarious way of computing, and must always be corrected by experience and good sense; there being a great deal of uncertainty in the yawing of the ship going with the wind aft, or upon the quarter in the heaving of it, by its coming home, or being drawn after the ship, on account of the friction of the reel and lightness of the log in the course of the current, and in the strength of the wind, which seldom keeps the same tenor for two hours together; which is the interval between the times of using the log in short voyages, though in longer ones they heave it every hour. Yet this is a much more exact way of computing than any other in use; much preferable certainly to that of the Spaniards and Portuguese, who guessed at the ship's way by the running of the froth or water by the ship's side; or to that of the Dutch, who used to heave a chip over-board, and to number the paces they walk on the deck while the chip swims between any two marks, or bulk-heads on the side.

Compound Log. The above mentioned errors, and particularly the log's being subject to drive with the motion which the water may have at its surface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been considered by writers, and many methods have been proposed to remove, or at least to lessen them.

Log.

Log. The late M. Bouguer proposed a method, which has been thought deserving of particular attention, in the Mem. Acad. Sc. 1747; afterwards in his *Treatise on Navigation*, published at Paris in 1753, and since reprinted in 1760, by the abbé de la Caille. For this purpose, take for the log a conical piece of wood, which fix to the log-line passed through or along its axis, at about 40, 50, or 60, or more feet, from one end; and to this end fix the diver, which is a body formed of two equal square pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals; and its size is fitted to that of the cone, that the whole may float. A cone of three inches diameter in the base, and of six inches in the slant height, is proposed by M. Bouguer to suit a diver made of plates about 9½ inches square; the intersection of the diagonals is joined to the log-line, and the loop and peg fixed as in the common log. However, it has been found, that no kind of wood used in British dock-yards, when formed into a cone of the above dimensions, will float a diver made of stout tin plates, one side of the square being 9½ inches. Such a diver weighing 1½ lb avoirdupois, required to float it a cone of five inches diameter and twelve inches on the slant side, so as the point of the cone, which was made of light fir, should just appear above the water. Now supposing one side of such a square tin-diver to be about ten inches, and made of plates only two-thirds of the thickness of the former, such a diver would weigh, with its folder, about 20 ounces, and can be floated by a light fir cone of four inches diameter in the base, and ten inches in the slant height or length; and such a compound log might perhaps be found on trial to be affected by about as much again as that proposed by M. Bouguer; and consequently the difference between the numbers given by the common log and compound log, must be augmented by two-thirds of itself for the necessary correction, as below. When the compound log of Bouguer, above described, is hove overboard, the diver will sink too deep to be much affected by the current or motion of water at the surface, and the log will thereby keep more steadily in the place where it first fell; and consequently the knots run off the reel will show more accurately the ship's rate of sailing. As the common log is affected by the whole motion of the current, so this compound log will feel only a part thereof, viz. such a part nearly as the resistance of the cone is to the resistance of the diver; then the resistances of the above cone and diver are about as 1 to 5; and consequently this log will drive but one-fifth part of what the common log would do; and so the ship's true run will be affected by one-fifth only of the motion of the waters. To obtain the true rate of sailing, it will be proper to heave alternately, hour and hour, the common log and this compound log; then the difference of their knots run off, augmented by its one-fourth part, is the correction; which applied to the knots of the common log, will give the ship's true rate of sailing at the middle time between the hours when these logs were hove. The correction is additive when the compound log's run is the greater, otherwise it is subtractive. To find the course made good: increase the observed angle between the log-lines by one-fourth part; and this gives the correction to be applied to the apparent course, or the opposite of that shown by

the common log; the correction is to be applied to the $\left\{ \begin{array}{l} \text{right} \\ \text{left} \end{array} \right\}$ of the apparent course, when the bearing of the common log is to the $\left\{ \begin{array}{l} \text{left} \\ \text{right} \end{array} \right\}$ of the compound log. Or thus: the lengths run off both logs, together with their bearings, being known; in a card or compass apply the knots run off, taken from a scale of equal parts along their respective bearings, from the centre; join the ends; and in this line produced, on the side next the compound log's length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the centre of the card, will show the true course and distance made good. When a current, such as a tide, runs to any depth, the velocity of that current may be much better ascertained by the compound log than by the common one, provided the diver does not descend lower than the run of the current; for as those ships which are deeply immersed, drive faster with the tide; so the diver, by being acted on below, as well as the log on the surface, their joint motion will give the total effect of the current's motion better than what could be derived from the motion at the surface only. Also, by such a compound log, the depth to which any current runs may be easily tried.

Other Logs. We have an account in the voyage to the North Pole, p. 97, of two other logs, which were tried by captain Phipps: one invented by Mr Ruffel, the other by Foxon; both constructed upon this principle, that a spiral, in proceeding its own length in the direction of its axis through a resisting medium, makes one revolution round the axis; if, therefore, the revolutions of the spiral are registered, the number of times it has gone its own length through the water will be known. In both these the motion of the spiral in the water is communicated to the clock-work within-board, by means of a small line fastened at one end to the spiral, which tows it after the ship, and at the other to a spindle, which sets the clock-work in motion. That invented by Mr Ruffel has a half-spiral of two threads, made of copper, and a small dial with clock-work, to register the number of turns of the spiral. The other log has a whole spiral of wood with one thread, and a larger piece of clock-work with three dials, two of them to mark the distance, and the other divided into knots and fathoms, to show the rate by the half-minute glass, for the convenience of comparing it with the log. This kind of log will have the advantage of every other in smooth water and moderate weather; and it will be useful in finding the trim of a ship when alone, in surveying a coast in a single ship, or in measuring distances in a boat between head-lands and shoals; but it is subject to other inconveniences, which will not render it a proper substitute for the common log.

Perpetual Log. a machine so called by its inventor, Mr Gottlieb of Houndditch, London. It is intended by it to keep a constant and regular account of the rate of the ship's velocity through the water; whereas the common log hitherto used does not indicate the variation in her velocity in the interval of heaving the log, and consequently does not ascertain the true distance that the ship has run in any given length of time.

Log.

Log.

Plate
CLXXXIII

Fig. 1. is a representation of the whole machine; the lower part of which, EFG, is fixed to the side of the keel; H representing only the boundary line of the ship's figure. EF are the section of a wooden external case, left open at the ends KL, to admit the passage of the water during the motion of the ship. At M is a copper grating, placed to obstruct the entrance of any dirt, &c. into the machine. I, is a section of a water-wheel, made from 6 to 12 inches in diameter, as may be necessary, with float-boards upon its circumference, like a common water-wheel, that turn by the resistance of the water passing through the channel LK. It turns upon a shouldered axis, represented by the vertical section at K. When the ship is in motion, the resistance of the water through the channel LK turns round the wheel I. This wheel, by means of a pinion, is connected with and turns the rod contained in the long copper tube N. This rod, by a pinion fixed at its upper extremity, is connected with and turns upon the whole system of wheels contained in the dial of the case ABCD. This dial, by means of the copper tube N, may be fixed to any convenient place aboard the ship. In the front of the dial are several useful circular graduations, as follow: The reference by the dotted line A has an hand which is moved by the wheels within, which points out the motion of the ship in fathoms of 6 feet each. The circle at B has an hand showing the knots, at the rate of 48 feet for each knot; and is to be observed with the half-minute glass at any time. The circle at C has a short and a long hand; the former of which points out the miles in land measure, and the latter or longer the number of knots contained in each mile, viz. 128, which is in the same proportion to a mile as 60 minutes to the hour in the reckoning. At e, a small portion of a circle is seen through the front-plate called the *register*; which shows, in the course of 24 hours (if the ship is upon one tack), the distance in miles that she has run; and in the 24 hours the mariner need take but one observation, as this register serves as an useful check upon the fathoms, knots, and miles, shown upon the two other circles.

f, Is a plate showing 100 degrees or 6000 miles, and also acts as another register or check; and is useful

in case of any mistake being made in observing the distance run by the other circles. The reckoning by these circles, without fear of mistake, may therefore be continued to nearly 12,000 miles.

A communication from this machine may easily be made to the captain's bed-side, where by touching a spring only, a bell in the head ABCD will sound as many times in an half minute as the ship sails miles in an hour.

Mr Gottlieb has applied this machine to the Carteret and Westmoreland packets. He is very sanguine in the hopes of its success and utility; and conceives that the mariner will, by this contrivance, be better enabled than heretofore to keep the vessel and his reckoning together; it being well known that the most experienced navigator is too frequently erroneous in this respect, the ship being sometimes ahead, or sometimes astern, off the reckoning.

He also observes, that the construction of the log is such, that if the vessel was to be aground, strike a rock, or strip off her false keel, the parts would not be deranged: and further, should she be laid up for repairs, &c. six months, in half an hour after coming again into the water, the lower immersed part of the log would clear itself, and be in proper action.

Log-Board, a sort of table, divided into several columns, containing the hours of the day and night, the direction of the winds, the course of the ship, and all the material occurrences that happen during the 24 hours, or from noon to noon; together with the latitude by observation. From this table the different officers of the ship are furnished with materials to compile their journals, wherein they likewise insert whatever may have been omitted, or reject what may appear superfluous in the log-board.

Log-Book, a book into which the contents of the log-board is daily copied at noon, together with every circumstance deserving notice that may happen to the ship, or within her cognizance, either at sea or in a harbour, &c. The intermediate divisions or watches of the log-book, containing four hours each, are usually signed by the commanding officer in ships of war or East-Indiamen. See NAVIGATION.

L O G A R I T H M S.

LOGARITHMS, (from *λογος* ratio, and *αριθμος* number), the indices of the ratios of numbers to one another; being a series of numbers in arithmetical progression, corresponding to others in geometrical progression; by means of which, arithmetical calculations can be made with much more ease and expedition than otherwise.

SECT. I. History of Logarithms.

THE invention of logarithms first occurred to those versant in the construction of trigonometrical tables, in which immense labour was required by large multiplications, divisions, and extraction of roots. The aim proposed was, to reduce as much as possible the mul-

tiplications and divisions to additions and subtractions; and for this purpose, a method was invented by Nicholas Raymer Ursus Dithmarfus, which serves for one case of the sines, viz. when the radius is the first term in proportion, and the sines of two arcs the second and third terms. In this case the fourth term is found by only taking half the sum or difference of the sines of the other two arcs, and the complement of the greater. This method was first published in 1588, and a few years afterward was greatly improved by Clavius, who used it in all proportions in the solution of spherical triangles; adapting it to sines, tangents, versed sines, and secants; and this, whether the radius was the first term in the proportion or not.

This method, however, though now become much more

more generally useful than before, was still found attended with trouble in some cases; and as it depended upon certain properties of lines belonging to the circle, was rather of a geometrical than arithmetical nature; on which account the calculators about the end of the 16th and beginning of the 17th century, finding the solution of astronomical problems extremely troublesome, by reason of the tedious multiplications and divisions they required, continued their endeavours to lessen that labour, by searching for a method of reducing their operations to addition and subtraction. The first step towards this was, the consideration, that as in multiplication the ratio of the multiplier to unity is the same as that of the product to the multiplicand, it will follow, that the ratio of the product to unity must be equal to the sum of the two ratios of the multiplier to unity, and of the multiplicand to unity. Could a set of numbers therefore be found, which would represent the ratios of all other numbers to unity, the addition of two of the former set of numbers would be equivalent to the multiplication of the two numbers together, the ratios of which they denoted; and the sum arising from this addition would denote the ratio of their product to unity; whence the product itself might be found by looking for the corresponding natural number in the table.

The next thing was to fall upon a method of calculating such a table as was wanted, which indeed appeared an Herculean labour. The first observation was, that whatever numbers might be made use of to represent the ratios of others, the ratio of equality, or that of unity to unity must be 0; for that ratio has properly no magnitude, neither increasing nor diminishing any other ratio to which it is adapted, or from which it is subtracted.

2. The second observation was, that though any number might be chosen at pleasure to represent the ratio of any other number to unity, yet when once this choice was made, all the other numbers representing the different ratios must be determined by it. Thus, if the ratio of 10 to 1 be represented by 1, then the ratio of 100 to 1 must be 2, and that of 1000 to 1 must be 3, &c.; or if 2 was chosen to represent the ratio of 10 to 1, then that of 100 to 1 must be 4, that of 1000 to 1 must be 6, &c.; and no other numbers could possibly be used.

3. As those artificial numbers represented, or were proportional to, the ratios of the natural numbers to unity, they must be expressions of the numbers of some smaller equal ratios contained in the former and larger ones. Thus, if we make 1 the representative of the ratio of 10 to 1; then 3, which represents the ratio of 1000 to 1, will likewise express the number of ratios of 10 to 1, which are contained in that of 1000 to 1. If instead of 1, we make 1000 to be the ratio of 10 to 1; then 3000 will express the ratio of 1000 to 1, and this number 3000 will express the number of small ratios of the 1000th root of 10 to 1 contained in the ratio of 1000 to 1; and so on for any larger number, as 10,000, 100,000, or 10,000,000, &c. Thus, if instead of 1000 we make 10,000,000 the representative of the ratio of 10 to 1, then the unit will represent a very small ratio, of which there are 10,000,000 contained betwixt 1 and 10, and which ratio could not really be had without extracting a root which involved

N^o 183.

in itself, 10,000,000 of times would only make up 10; which root may perhaps be most intelligibly expressed thus, $10,000,000 \sqrt{10}$. If the ratio of 10 to 1 contained 10,000,000 of these roots, it is evident that the ratio of 100 to 1 must contain 20,000,000, that of 1000 would have 30,000,000, &c.; of consequence, the ratio of 100 to 1 will be expressed by 20,000,000, of 1000 to 1 by 30,000,000, &c.—Hence, as these artificial numbers represent the ratios of natural numbers to unity, or are proportional to them, they are very properly called the *logarithms* of these numbers, or the *numbers of their ratios*; because they really do express this number of ratios.

The relation of logarithms to natural numbers may perhaps more intelligibly be explained by two series of numbers, one in an arithmetical, and the other in geometrical, progression. Thus,

Logarithms, 0	1	2	3	4	5	6	7	8
Nat. numb. 1	2	4	8	16	32	64	128	256

Or,

Logarithms, 0	1	2	3	4	5	6
Nat. numb. 1	10	100	1000	10,000	100,000	1,000,000

In either of these series it is evident, that by adding any two terms of the upper line together, a number will be had which indicates that produced by multiplying the corresponding terms of the lower line. Thus, in the first two series, suppose we wish to know the product of 4×32 . In the upper line we find 2 standing over the number 4, and 5 over 32; adding therefore 5 to 2 we find 7, the sum of this addition, standing over 128, the product of the two numbers. In like manner, if we wish to divide 256 by 8, from the number which stands over 256, viz. 8, subtract that which stands over 8, viz. 3; the remainder 5, which stands over 32, shows that the latter is the quotient of 256 divided by 8. Let it be required to involve 4 as high as the biquadrate or 4th power: Multiply 2, the number which stands over 4, by the index of the power to which the number is to be involved; which index is 4: the product 8, standing over 256, shows that this last number is the biquadrate of 4 required. Lastly, let it be required to extract the cube root of 64; divide the number 6, which stands over 64, by 3, the index of the root you wish to extract; the quotient 2, standing over 4, shows that 4 is the root sought.

These examples are sufficient to show the great utility of logarithms in the most tedious and difficult parts of arithmetic. But though it is thus easy to frame a table of logarithms for any series of numbers going on in geometrical progression, yet it must be far more difficult to frame a general table in which the logarithms of every possible series of geometricals shall correspond with each other. Thus, though in the above series we can easily find the logarithm of 4, 8, &c. we cannot find that of 3, 6, 9, &c.; and if we assume any random numbers for them, they will not correspond with those which have already been assumed for 4, 8, 16, &c. In the construction of every table, however, it was evident, that the arithmetical or logarithmic series ought to begin with 0; for if it began with unity, then the sum of the logarithms of any two numbers must be diminished by unity before we could find the logarithm of the product. Thus,

Logar. 1	2	3	4	5	6	7	8	9
Nat. N. 1	2	4	8	16	32	64	128	256

Here

Here let it be required to multiply 4 by 16; the number 3 standing over 4, added to 5 which stands over 16, gives 8 which stands over 128: but this is not just; so that we must diminish the logarithm by 1, and then the number 7 standing over 64 shows the true product. In like manner it appears, that as we descend below unity in a logarithmic table, the logarithms themselves must begin in a negative series with respect to the former; and thus the logarithm of 0 will always be infinite; negative, if the logarithms increase with the natural numbers; but positive, if they decrease. For as the geometrical series must diminish by infinite divisions by the common ratio, the arithmetical one must decrease by infinite subtractions, or increase by infinite additions of the common difference.

This property of numbers was not unknown to the ancient mathematicians. It is mentioned in the works of Euclid; and Archimedes made great use of it in his *Arenarius*, or treatise on the number of the sands: and it is probable that logarithms would have been much sooner invented, had the real necessity for them been sooner felt; but this did not take place till the end of the 16th century, when the construction of trigonometrical tables, and solution of perplexed astronomical problems, rendered them absolutely indispensable.

About this time it is probable that many people wished to see such tables of numbers, and were making attempts to construct them; but the invention is certainly due to Lord Napier, baron of Merchiston in Scotland. The invention is by some indeed ascribed to Longomontanus; but with very little probability, as he never published any thing of the kind, nor laid claim to the invention, though he lived to see the publication of Baron Napier's tables. Concerning this invention we are told, that "one Dr Craig a Scotchman, coming out of Denmark into his own country, called upon Baron Napier, and told him of an invention of Longomontanus in Denmark, to save the trouble of the tedious multiplication and division in astronomical calculations; but could give no farther account of it than that it was by proportionable numbers. From this slight hint the baron immediately set about the work; and by the time that Dr Craig returned to call upon him, he had prepared a rude draught of it, which he called *Canon mirabilis Logarithmorum*; and this draught, with some alterations, was printed in 1614.

According to Kepler, one Juste Byrge, assistant astronomer to the landgrave of Hesse, either invented or projected logarithms long before Baron Napier, and composed a table of sines for every two seconds of the quadrant; though, by reason of his natural reservedness, he never published any thing to the world. But whatever might have been in this, it is certain that the world is indebted for logarithms to Baron Napier, who died in the year 1618. This nobleman likewise made considerable improvements in trigonometry; and the frequent numerical computations he had occasion for in this branch, undoubtedly contributed to his invention of the logarithms, that he might save part of the trouble in these calculations. His book published in 1614 was intitled *Mirifici Logarithmorum Canonis descriptio*. At this time he did not publish his method of constructing the numbers until

the sense of the learned should be known. In other respects the work is complete, containing all the logarithms of the natural numbers to the usual extent of logarithmic tables; with the logarithmic sines, tangents, and secants, for every minute of the quadrant, directions for using the tables, &c.

This work was published in Latin; but was afterwards translated into English by Mr Edward Wright, inventor of the principles of what has been falsely called *Mercator's Sailing*. The translation was sent to his lordship at Edinburgh, and returned with his approbation and some few additions. It was published in 1616, after Mr Wright's death, with a dedication to the East India Company, by his son Samuel Wright, and a preface by Mr Briggs, who afterwards distinguished himself so much in bringing logarithms to perfection. In this translation Mr Briggs also gave the description and draught of a scale invented by Mr Wright, as well as other methods invented by himself, for finding the intermediate proportional numbers; the logarithms already found having been only printed for such numbers as were the natural sines of each minute.

Mr Wright's translation was reprinted in 1618, with a new title-page, and the addition of 16 pages of new matter, "showing the method of calculating triangles, as well as a method of finding out such lines and logarithms as are not to be found in the canons."

Next year John Speidell published his *New Logarithms*, in which were some remedies for the inconveniences attending Lord Napier's method. The same year also Robert Napier, the Baron's son, published a new edition of his father's book, entitled *Canonis Logarithmorum Descriptio*; with another concerning the method of constructing them, which the Baron had promised; together with some other miscellaneous pieces, which his father had likewise composed along with Mr Briggs. In 1620 also, a copy of these works was printed at Lyons in one volume, by Bartholomew Vincent a bookseller there; but this publication seems to have been but little known, as Wingate, who carried logarithms to France four years after, is said to have been the first who introduced them into that country.

The *Curfus Mathematicus* published at Cologne in 1618 or 1619 by Benjamin Ursinus, mathematician to the elector of Brandenburg, contains a copy of Napier's logarithms, together with some tables of proportional parts. In 1624 he published his *Trigonometria*, with a table of natural sines and their logarithms, according to Lord Napier's method, to every ten seconds in the quadrant. The same year a book on logarithms was published at Marburg by the celebrated Kepler, of the same kind with those of Napier. Both of these begin at 90° or the end of the quadrant; and, while the sines decrease, the logarithms gradually increase; till at the beginning of the quadrant, or 0, the logarithm is infinite. The only difference betwixt the logarithms of Napier and Kepler is, that in the former the arc is divided into equal parts, differing by one minute each; and consequently their sines to which the logarithms are adapted are interminate numbers represented only by approximating decimals: but in Kepler's table, the radius is divided into equal parts, which are considered as perfect and terminate sines, having equal differences, and to which the logarithms are here

adapted. A treatise of some extent was prefixed to the work; in which the construction and use of logarithms is pretty largely treated of. In the year 1627 the same author introduced logarithms into his Rudolphine Tables, together with several others, *viz.* 1. A table similar to that already mentioned; only that the column of sines or absolute numbers is omitted, and another added in its stead, showing what part of the quadrant each arc is equal to; *viz.* the quotient arising from the division of the whole quadrant by each given arc, and expressed in integers and sexagesimal parts. 2. Napier's table of logarithmic sines to every minute of the quadrant; as also two other smaller tables adapted for the calculation of eclipses and the latitude of planets. In this work Juitus Byrgius is mentioned as having invented logarithms before Napier.

The kind of logarithms now in use were invented by Mr Henry Briggs professor of geometry in Gresham college, London, at the time they were first discovered by Napier. As soon as the logarithms of Napier were published, Mr Briggs directed his attention to the study and improvement of them; and his employment in this way was announced in a letter to Mr Usher, afterwards the celebrated archbishop, in the year 1615. By him the scale was changed, and 0 was made the logarithm of 1; but lord Napier informed Mr Briggs that he had already thought of such a scheme, but chose rather to publish the logarithmic tables he had completed, and to let those alone until he should have more leisure as well as better health. At an interview betwixt Lord Napier and Mr Briggs, the present plan seems to have been settled; and in consequence of his lordship's advice, Mr Briggs made some alteration in the method of constructing his tables from that which he had begun. A correspondence also took place betwixt his lordship and Mr Briggs, which continued during the lifetime of the former. It appears, however, that, whether Mr Briggs thought of this alteration before lord Napier or not, he certainly was the person who first published it to the world; and some reflections have been thrown upon his lordship for not making any mention of the share which Mr Briggs had in it.

In 1617 Mr Briggs published his first thousand logarithms under the title of *Logarithmorum Chilias Primæ*; and in 1620 Mr Edward Gunter published his Canon of Triangles, containing the artificial or logarithmic sines and tangents for every minute, to seven places of figures besides the index; the logarithm of the radius being 10,000, &c. These were the first tables of logarithmic sines, tangents, &c. which made their appearance upon the present plan; and in 1623 they were reprinted in his book de *Scilore et Radio*, along with the *Chilias Prima* of Mr Briggs. The same year Mr Gunter applied these logarithms of numbers, sines, and tangents, to straight lines drawn on a ruler; and with these the proportions in common numbers, as well as in trigonometry, were solved by the mere application of a pair of compasses; a method founded upon this property, that the logarithms of the terms of equal ratios are equally different. The instrument is now well known by the name of the two-feet Gunter's Scale. By the same methods he also greatly improved the sector. He was also the first who used the word *cosine*

for the sine of the complement of an arc; and he introduced the use of arithmetical complements into the logarithmical arithmetic. He is said also to have first suggested the idea of the logarithmic curve, so called because the segments of its axis are the logarithms of the corresponding ordinates.

The logarithmic lines were afterwards drawn in many other ways. Wingate, in 1627, drew them upon two separate rulers sliding by each other, in order to save the use of compasses in resolving proportions. In 1627 also, they were applied by Mr Oughtred to concentric circles; about 1650, in a spiral form, by one Mr Milburne of Yorkshire; and in 1657, they were applied on the present sliding-rule by Mr Seth Partridge.

The knowledge of logarithms was diffused in France by Mr Edmund Wingate, as already related, though not carried originally thither by him. Two small tracts were published by him in French, and afterwards an edition in English, all printed in London. In the first of these he mentions the use of Gunter's Ruler; and in the other that of Briggs's Logarithms, with the canon of artificial sines and tangents. There are likewise tables of these sines, tangents, and logarithms, copied from Gunter.

From the time that Mr Briggs first began to study the nature of logarithms, he applied to the construction of tables with such assiduity, that by the year 1624 he published his *Arithmetica Logarithmica*, containing the logarithms of 30,000 natural numbers to 14 places of figures besides the index; *viz.* from 1 to 20,000, and from 90,000 to 100,000, together with the differences of the logarithms. According to some, there was another *Chilias*, *viz.* from 100,000 to 101,000; but this does not seem to be well authenticated. In the preface to this work, he gives an account of the alteration made in the scale by Lord Napier and himself; and earnestly solicits other persons to undertake the task of filling up the intermediate numbers; offering to give instructions, and to afford paper ready ruled for the purpose. He gives also instructions at large in the preface for the construction of logarithmic tables. Thus he hoped to get the logarithms of the other 70,000 natural numbers completed; while he himself, being now pretty far advanced in years, might be at liberty to apply to the canon of logarithmic sines, &c. which was as much wanted by mathematicians as the others. His wishes were accomplished by Adrian Vlaeq or Flaek of Gouda in Holland, who completed the numbers from 20 to 90,000; and thus the world was furnished with the logarithms of all natural numbers from 1 to 100,000; but those of Vlaeq were only done to 10 places of figures. To these was added a table of artificial sines, tangents, and secants, to every minute of the quadrant. Besides the great work already mentioned, Mr Briggs completed a table of logarithmic sines and tangents for the 100th part of every degree, to 14 places of figures besides the index; and a table of natural sines for the same parts to 15 places, with the tangents and secants to 10 places, and the methods of constructing them. He designed also to have published a treatise concerning the uses and application of them, but died before this could be accomplished. On his death-bed he recommended this work to Henry Gellibrand professor of astronomy.

astronomy in Gresham college, in which office he had succeeded Mr Gunter. Mr Briggs's tables above mentioned were printed at Gouda, and published in 1633; and the same year Mr Gellibrand added a preface with the application of logarithms to plane and spherical trigonometry, the whole being denominated *Trigonometria Britannica*: and besides the arcs in degrees and hundredth parts, has another table containing the minutes and seconds answering to the several hundredth parts in the first column.

The *Trigonometria Artificialis* of Vlacq contains the logarithmic fines and tangents to 10 places of figures, to which is added Briggs's first table of logarithms from 1 to 20,000, besides the index: The whole preceded by a description of the tables, and the application of them to plane and spherical trigonometry, chiefly extracted from Briggs's *Trigonometria Britannica* already mentioned. In 1635, Mr Gellibrand also published a work, intitled, *An Inquisition Trigonometrical*, containing the logarithms of the first 10,000 numbers, with the natural fines, tangents, and secants; and the logarithmic fines and tangents for degrees and minutes, all to seven places of figures besides the index; likewise other tables proper for navigation, with the uses of the whole. Mr Gellibrand died in 1636, in the 40th year of his age.

A number of other people have published books on logarithms, which we cannot now particularly enumerate. Some of the principal are:

1. A treatise concerning Briggs's logarithms of common numbers from 1 to 20,000, to 11 places of figures, with the logarithmic fines and tangents but only to eight places. By D. Henrion at Paris, 1626.

2. Briggs's logarithms, with their differences to 10 places of figures, besides the index for all numbers to 100,000; as also the logarithmic fines, tangents, and secants, for every minute of the quadrant, with the explanation and uses in English. By George Miller, London, 1631.

3. *Trigonometria*, by Richard Norwood, 1631; containing Briggs's logarithms from 1 to 10,000, as well as for the fines, tangents, and secants to every minute, both to several places of figures besides the index. The author complains very much of the unfair practices of both the former authors.

4. *Directorium Generale Uranometricum*; by Francis Bonaventura Cavalieri. Bologna, 1632. In this are Mr Briggs's tables of logarithmic fines, tangents, secants, and versed fines each to eight places of figures for every second of the first 5 minutes, for every 5 seconds from 5 to 10 minutes, for every 20 seconds from 20 to 30 minutes, for every 30 seconds from 30 minutes to 15 degree, and for every minute in the rest of the quadrant. It contains also the logarithms of natural numbers from 1 to 10,000, with the first table of versed fines that ever was published. The author likewise gives the first intimation of the method of finding the arcs or spherical surface contained by various arcs described on the surface of a sphere.

5. In 1643 appeared the *Trigonometria* of the same author, containing the logarithms of the natural numbers from 1 to 1000, with their differences to eight places of figures; likewise a table of natural logarithmic fines, tangents, and secants; the former to seven, the latter to eight, places of figures; viz. to

every 10' of the first 30', to every 30' from 30' to 1°, and the same for their complements, or backwards thro' the last degree of the quadrant; the intermediate 88° being only to every minute.

6. *Tabule Logarithmicæ*; by Mr Nathaniel Rowe, pastor of Benaire in Suffolk: Lond. 1633. In this work are contained Briggs's logarithms of natural numbers from 1 to 100,000, to eight places of figures; likewise the logarithmic fines and tangents to every 100th part of degrees to ten places.

7. *Clavis Univerſa Trigonometria*; Hamburg, 1634: containing tables of Briggs's logarithms from 1 to 2000; and of fines, tangents, and secants, for every minute, both for seven places.

8. *Trigonometria Britannica*, by John Newton, London, 1658. In this the logarithmic tables of natural numbers were reduced to their most convenient form; the author having availed himself of the labours of Wingate and Roe, uniting their several methods, and disposing of the whole as in the best logarithmic tables used at present. It contains likewise the logarithmic fines and tangents to eight figures besides the index; for every hundredth part of a degree, with the differences, and for thousandth parts in the first three degrees. He censures the unfair practices of some former publishers of logarithms; particularly of Vlacq already mentioned.

9. *Mathesis Nova*, by John Caramuel, 1670. This contained 1000 logarithms, both of the forms of Napier and Briggs, as well as 1000 of what he calls *perfect logarithms*, viz. those of Briggs's first method of construction; which differs from the last only in this, that the last increases, whilst the first decreases; the radix or logarithm of the ratio of 10 to 1 being the very same in both.

10. Sherwin's Mathematical Tables, published in 8vo, form the most complete collection of any; containing, besides the logarithms of all numbers to 1:1,000, the fines, tangents, secants, versed fines both natural and logarithmic, to every minute of the quadrant. The first edition was printed in 1706; but the third, published in 1742 and revised by Gardiner, is looked upon to be superior to any other. The fifth and last edition, published in 1771, is so incorrect, that no dependence can be placed upon it.

11. Tables of logarithms from 1 to 102,100, and for the fines and tangents to every 10 seconds of each degree in the quadrant; as also for the fines of the first 72 minutes to every single second, with other useful and necessary tables. By Gardiner, London, 1742. This work contains a table of logarithmic logarithms, and three smaller tables to be used for finding the logarithms of numbers to 20 places of figures. Only a small number of these tables was printed, and that by subscription; and they are now in the highest esteem for accuracy and usefulness. An edition of these tables was printed at Avignon in France in 1770, with the addition of fines and tangents for every single second in the first four degrees, and a small table of hyperbolic logarithms, taken from a treatise upon fluxions by the late Mr Thomas Simson. The tables are to seven places of figures, but somewhat less correct than those published by Gardiner himself.

12. An Antilogarithmic Canon for readily finding the number corresponding to any logarithm, was begun by

Construc-
tion of
Logarithms

the algebraist Mr Harriot, who died in 1621; and completed by Mr Walter Warner, the editor of Harriot's works, before 1640, but never was published for want of encouragement to print it. In 1714 a small specimen of such a canon appeared in the Philosophical Transactions for that year by Mr Long of Oxford; and in 1742 a complete Antilogarithmic Canon appeared by Mr James Dodson, in which the numbers corresponding to each logarithm from 1 to 100,000 are computed to 11 places of figures.

12. In 1783 were published M. Callet's tables at Paris; which for the elegance of the workmanship are much superior to any thing of the kind that ever appeared, though their accuracy is not esteemed equal to that of some others. The work is a neat volume small 8vo. It contains a treatise on logarithms; with their uses and application to various sciences; as trigonometry, astronomy, and navigation; a table of logarithms from 1 to 102,960, with the differences; a table of sines and tangents for every single second of the first two degrees, and for every 10 seconds of the rest of the quadrant; with tables of logistical and hyperbolic logarithms, and some others for determining the longitude at sea.

SECT. II. Different methods of constructing Logarithms.

§. 1. Napier's method.

THE logarithms first thought of by Lord Napier were not adapted to the natural series of arithmetical numbers 1, 2, 3, &c. because he did not then intend to adapt them to every kind of arithmetical calculation, but only to that particular operation which had called for their immediate construction, viz. the shortening of trigonometrical operations: he explained the generation of logarithms, therefore, in a geometrical way. Both logarithms, and the quantities to which they correspond, in his way, may be supposed to proceed from the motion of a point; which, if it moves over equal spaces in equal times, will produce a line increasing equally: but if, instead of moving over equal spaces in equal times, the point describes spaces proportional to its distances from a certain term, the line produced by it will then increase proportionably. Again, if the point moves over such spaces in equal times, as are always in the same constant ratio to the lines from which they are subducted, or to the distance of that point at the beginning of the lines, from a given term in that line, the line so produced will decrease proportionably. Thus, let ac be to ao , cd to co , ef to fo , and fg to fo , always in a certain ratio, viz. that of QR to QS , and let us suppose the point P to set f out from a , describing the distances ac , cd , de , &c. in equal spaces of time, then will the line ao decrease proportionably.

In like manner, the line oa , (fig. 12.) increases proportionally, if the point p , in equal times, describes the spaces ac , cd , de , fg , &c. so that ac is to ao , cd to co , de to do , &c. in a constant ratio. If we now suppose a point P describing the line AG (fig. 4.) with a uniform motion, while the point p describes a line increasing or decreasing proportionally, the line

AP , described by P , with this uniform motion, in the same time that oa , by increasing or decreasing proportionally, becomes equal to op , is the logarithm of op . Thus AC , AD , AE , &c. are the logarithms of oc , od , oe , &c. respectively: and oa is the quantity whose logarithm is supposed equal to nothing.

We have here abstracted from numbers, that the doctrine may be the more general; but it is plain, that if AC , AD , AE , &c. be supposed 1, 2, 3, &c. in arithmetic progression; oc , od , oe , &c. will be in geometric progression; and that the logarithm of oa , which may be taken for unity, is nothing.

Lord Napier, in his first scheme of logarithms, supposes, that while op increases or decreases proportionally, the uniform motion of the point P , by which the logarithm of op is generated, is equal to the velocity of p at a ; that is, at the term of time when the logarithms begin to be generated. Hence logarithms, formed after this model, are called Napier's Logarithms, and sometimes Natural Logarithms.

When a ratio is given, the point p describes the difference of the terms of the ratio at the same time. When a ratio is duplicate of another ratio, the point p describes the difference of the terms in a double time. When a ratio is triplicate of another, it describes the difference of the terms in a triple time; and so on. Also, when a ratio is compounded of two or more ratios, the point p describes the difference of the terms of that ratio in a time equal to the sum of the times in which it describes the differences of the terms of the simple ratios of which it is compounded. And what is here said of the times of the motion of p when op increases proportionally, is to be applied to the spaces described by P , in those times, with its uniform motion.

Hence the chief properties of logarithms are deduced. They are the measures of ratios. The excess of the logarithm of the antecedent above the logarithm of the consequent, measures the ratio of those terms. The measure of the ratio of a greater quantity to a lesser is positive; as this ratio, compounded with any other ratio, increases it. The ratio of equality, compounded with any other ratio, neither increases nor diminishes it; and its measure is nothing. The measure of the ratio of a lesser quantity to a greater is negative; as this ratio, compounded with any other ratio, diminishes it. The ratio of any quantity A to unity, compounded with the ratio of unity to A , produces the ratio of A to A , or the ratio of equality; and the measures of those two ratios destroy each other when added together; so that when the one is considered as positive, the other is to be considered as negative. By supposing the logarithms of quantities greater than oa (which is supposed to represent unity) to be positive, and the logarithms of quantities less than it to be negative, the same rules serve for the operations by logarithms, whether the quantities be greater or less than ao . When op increases proportionally, the motion of p is perpetually accelerated; for the spaces ac , cd , de , &c. that are described by it in any equal times that continually succeed after each other, perpetually increase in the same proportion as the lines ao , oc , od , &c. When the point p moves from a towards o , and op decreases proportionally, the motion of p is perpetually retarded; for the spaces described by it in any equal times that

Construc-
tion of
Logarithms

Plate
CCLXXIII
fig. 1, 2.

Construc-
tion of
Logarithms

continually succeed after each other, decrease in this case in the same proportion as op decreases.

If the velocity of the point p be always as the distance op , then will this line increase or decrease in the manner supposed by Lord Napier; and the velocity of the point p being the fluxion of the line op , will always vary in the same ratio as this quantity itself. This, we presume, will give a clear idea of the genesis or nature of logarithms; but for more of this doctrine, see Maclaurin's Fluxions.

The construction of his tables of logarithms was first published in his posthumous work of 1619. The construction of his canon was chiefly effected by generating, in an easy manner, a series of proportional numbers, and their arithmeticals or logarithms; and then finding by proportion the logarithms of the natural sines from those of the nearest numbers among the original proportionals. Beginning then at the radius 10,000,000, he first constructs several descending geometrical series, of such a nature that they are quickly formed by an easy addition or subtraction, or division by 2, 10, 100, &c. His first table consists of proportionals in the ratio of 10,000,000 to 9,999,999; the method of doing which may be easily understood from the following example: Suppose it were required to find a series of descending proportionals in the ratio of 100 to 99; it may be done by adding two cyphers to each of the two first terms, and continually adding 1 to the decimal place farthest to the right hand. Thus the first term will be 100.00, the second 99.00, the third 98.01, the fourth 98.03, &c. Napier's first table contained 100 terms of a series, as we already mentioned, in the proportion of 10,000,000 to 9,999,999. The first term of which series was 10,000,000.0000000; the second 9,999,999.0000000; the third was 9,999,998.0000001, and so on till the 100th term, which was 9,999,900.0004950. The second table consisted of 50 numbers nearly in the proportion of 100,000 to 99,999; and this was formed by substituting the units 1, 3, &c. in the third decimal place instead of the last place towards the right hand.

The reason of constructing this table was, that he might have a series in the proportion of his first term of the former to the last term of it, viz. of 100,000 to 99,999; and the last of the second series was 9995001.222927. In all these series the method of finding the terms is exactly the same. Thus in the first example, where we begin with 100, each term decreases by the 100th part of the former; and this 100th part is found by removing the number two places of figures lower, and subtracting them from the former terms. Thus 99 is less than 100 by unity, which is the 100th part of the latter; the next term is less than 99 by the 100th part of 99, and is therefore 98.01. But the division by 100 can be performed without any trouble, only setting the decimal point two places farther forward, as that by 10 is performed by setting it one place farther forward; thus $9 \div 10 = .9$; $99 \div 100 = .99$. Now by subtracting 99 from 100, we have 98.01 for the third term of the series. To find the fourth term then, remove the decimal point two figures farther to the right hand, and subtract it from the former; and we have then 97.0299 for the fourth term of the series. Thus we see, that the number of decimal places must continually increase; but as in this series we want no more than two decimal

Construc-
tion of
Logarithms

places instead of 97,0299, the term is made 97.03, as the nearest number which has only two decimal places, and differs from the truth only by one thousandth part. In like manner, in the long string of cyphers, the fourth term of the series differs somewhat, but very little, from the truth; and this must always be the case while the radius is supposed to consist of any finite number of parts; though, by going on for a very long time in this way, the error, by being continually repeated and augmented at every term, would at last become perceptible; and therefore none of these series are carried on to a very great length.

His next step was to construct a third table consisting of 69 columns; and each column of 21 numbers or terms in the continual proportion of 10000 to 9995; that is, nearly as the first term of the second table is to its last term. As this proportion is the 2000th of the whole, the method of finding the terms will be by dividing each upper number by 2, and removing the figures of the quotient three places lower, and then subtracting them. In this way, however, it is proper to collect only the first column of 21 numbers, the last of which will be 9900473.5780; but the first, second, and third, &c. numbers in all the other columns are in the continual proportion of 100 to 99, or nearly of the first to the last in the first column; whence these are to be found by removing the figures two places lower, and then subtracting them, as has already been explained.

By these three tables, his lordship was furnished with about 1600 proportionals, nearly coinciding with all the natural series from 90 to 30 degrees. To obtain the logarithms of those proportionals, he demonstrated and applied some of the properties and relations of the numbers and logarithms; the principal of which are, 1. That the logarithm of any fine is greater than the difference between that fine and the radius, but less than that difference when increased in the proportion of the fine to the radius. 2. That the difference between the logarithms of two fines is less than the difference of the fines increased in the proportion of the lesser fine to the radius, but greater than the difference of the fines increased in the proportion of the greater fine to the radius. These properties now served him as theorems for finding the logarithms themselves in an easy manner. From the first of them it appeared, that the radius being 10,000,000, the first term of the table, the logarithm of 9,999,999, the second term, must be greater than the difference betwixt that term and the radius, which is 1, but less than the difference when increased in the proportion of the fine to the radius; but this proportion is only one ten millionth part, for $9,999,999 \times 1.0000001 = 10,000,000$; whence the logarithm of the radius or 10,000,000 being 0, the logarithm of 9,999,999 the second term will be between 1 and 1.0000001, or very nearly 1.00000005, this being the arithmetical mean betwixt 1 and 1.0000001. This will also be the common difference betwixt every two succeeding terms in the first table; because all the terms there are in the same proportion of 10,000,000 to 9,999,999. Hence by the continual addition of this logarithm we have the logarithms of the whole series, and therefore that of the last term of the series viz. 9999900.0004950 will be 100.000005.

The second table, as we have already said, consists

Construc-
tion of
Logarithms

of a series of numbers in the continual proportion of 100000 to 99999, whence the first term being 10,000,000 the second will be 9,999,900; the difference betwixt this and the last term of the former series is .0004950. But by the second theorem, the difference between the logarithms of 9,999,900,0004950 and 9,999,900, the second term of the second table, will be less than .0004950, increased in the proportion of 99999 to 100000, but greater than .0004950, increased in the proportion of 9,999,900,0004950; that is to say, if we augment .0004950 by one hundred thousandth part, it will be greater than the difference betwixt the logarithms of the two terms. The limits, therefore, are here so extremely small, that we may account the difference betwixt the two terms and that of the logarithms themselves the same: adding therefore this difference .0004950 to 100,000,000, we have 100,000,000 for the logarithm of the second term, and likewise for the common difference of all the logarithms of the terms of the second table. — Again, by the same theorem, the difference between the logarithms of this last proportional of the second table and the second term in the first column of the third table, will be found to be 1.2235287; which added to the last logarithm, gives 5001.2485387 for the logarithm of 9,995,000, the second term of the third table: and in a similar manner, by the same theorem, he finds the logarithms of all the other terms of the rest of the columns.

Thus our author completed what he calls his radical table, from which he found his logarithmic sines by taking, according to the second theorem, the sum and difference of each tabular sine, and the nearest number in the radical table. Annex then seven ciphers to the difference; divide the number by the sum, and half the quotient will be the difference between the logarithms of the tabular sine and radical number; and consequently, by adding or subtracting this difference to or from the logarithm of the natural number, we have the logarithmic sine required.

In this manner were completed the logarithmic sines from radius or sine of 90° to the half of it, or sine of 30°. To complete the other 30°, he observes, that the logarithm of the ratio of 2 to 1, or of one half the radius, is 6931469.22; that of the ratio of 4 to 1 is double of it; that of 8 to 1, triple of it, &c.; and thus going on to compute the logarithms of the ratio between 1 and 40, 80, 100, &c. to 10,000,000; then multiplying any given sine for an arc less than 30° by some of these numbers, he finds the product nearly equal to some number in the table; and then finds the logarithm by the second theorem as already directed.

Another, and much easier method, however, of performing the same thing is founded upon the following proportion, which he demonstrates, *viz.* that as half the radius is to the sine of half an arc, so is the cosine of the half arc to the sine of the whole arc; or as one half the radius is to the sine of any arc, so is the cosine of that arc to the sine of double the arc. Hence the logarithmic sine of an arc is found by adding the logarithms of half the radius and the sine of double the arc, and then subtracting the logarithmic cosine from the sum. In this way, he observes that the sines for full one half of the quadrant may be found, and the remainder by one easy division, or

addition and subtraction for each, as already directed.

Construc-
tion of
Logarithms

§. 2. Kepler's method of construction.

This was founded upon principles nearly similar to that of Napier. He first of all erects a system of proportions, and the measures of proportion, founded upon principles purely mathematical; after which he applies these principles to the construction of his table, containing only the logarithms of 1000 numbers. The propositions on which his method is founded are in substance the following.

1. All equal proportions equal among themselves are expressed by the same quantity, be the terms many or few; as the proportion of 2, 4, 8, &c. in geometrical progression is expressed by 2; and of 2, 6, 18, 54, &c. by 3.

2. Hence the proportion of the extremes is composed of all the proportions of the intermediate terms; thus the proportion of 2 to 8 its compounded of that 2 to 4, and of 4 to 8.

3. The mean proportional betwixt two terms divides that proportion into two equal ones. Thus the proportion between 2 and 32 is divided by the mean proportional 8 into two equal proportions of 4; for 2 is to 8, as 8 is to 32.

4. In any number of proportionals regularly increasing, the means divide the proportion of the extremes into one more than their own number. Thus, in the series 2, 4, 8, 16, the proportion of the extremes 2 and 16 is by the *two* means 4 and 8, divided into *three* proportions, *viz.* that betwixt 2 and 4, 4 and 8, 8 and 16. In like manner, in the series 3, 6, 18, 54, 162, 486, the proportion betwixt 3 and 486 is divided by the four means into the five proportions of 3 to 6; 6 to 18; 18 to 54; 54 to 162; and 162 to 486.

5. The proportion betwixt any two terms is divisible into any number of parts, until these become less than any assignable quantity. Thus the proportion of 2 to 8 is divisible, by multiplying the two together and extracting the square root, into two parts by the number 4: by multiplying 2 and 4 together, and extracting the square root, and doing the same with 4 and 8, the proportion would be divided into four parts, *viz.* $2/\sqrt{8}$, $4/\sqrt{32}$, &c. or in numbers, 2 : 2.813, &c. 14 : 5.655, &c.: 8.

6. By dividing the ratios in this manner, the elementary part will become at last so small, that it may be denominated by the mere difference of terms of that element. This is evident from the diminution of the ratios or proportions already instanced: for the proportion between 2 and 2.813 is only 1.406, &c. and if we were to find a mean proportional betwixt 2 and 2.813, the ratio betwixt that proportional and 2 would be much less. But it must always be remembered, that such *evanescent* quantities, as they are called, cannot give us any conclusion with absolute exactness, however they may answer every useful purpose to us: for it is evident that neither mean proportional nor ratio can ever be found exactly; and therefore the error accumulated in all the operations must become very considerable, if any circumstance shall happen to make it appear.

7. In three continued proportionals, the difference of

Construc-
tion of
Logarithms

Construc-
tion of
Logarithms

of the two first has to the difference between the two last the same proportion that the first term has to the second, or the second to the third. Thus, in the three terms, 4, 8, 16, the difference between the two first terms 4 and 8, viz. 4, is in proportion to 8; and the difference between the two last, as 4 is to 8, or 8 to 16.

8. In continued proportionals, the greatest terms have the greatest differences, and *vice versa*. Thus the difference between 8 and 16 is evidently greater than between 2 and 4 or 4 and 8.

9. If the difference betwixt the two greatest terms be made the measure of the proportion between them, the difference between any two others will be less than the true measure of their proportion. Thus in the series 4, 2, 1, $\frac{1}{2}$, $\frac{1}{4}$, &c. where the difference 2 betwixt the two greatest terms expresses their true proportion, it is plain, that the difference 1 betwixt 2 and 1 is less than their ratio, as well as between $\frac{1}{2}$ and $\frac{1}{4}$, &c.

10. In any series of proportionals, if the difference betwixt the greatest term and one not immediately next to it, be taken as the measure of the proportion, then the proportion betwixt the greatest term and any other greater than the term before taken, will be less than the difference of those terms; but the proportion which is between the greatest term and any one less than that first taken, will be greater than their difference. As proportionals of this kind do not readily occur, we shall, in order to avoid obscurity, shew once for all, that there is a possibility of finding geometrical proportionals of such a nature, that the ratio may be equal to the difference betwixt the greatest and third, or any other term distant from it. Thus let us begin with any two numbers we please, suppose 9 and 10: though these are in the natural arithmetical proportion, yet if we make the ratio 1.111, they will also be geometrically proportional, and the series will run thus:

1st	2d	3d	4th	5th	6th
term	term	term	term	term	term

10 : 9 : 8.099 : 7.289 : 6.560 : 5.904, &c.

Here the difference betwixt the first and third terms is 1.901, which is greater than the ratio; that betwixt the second and fourth, viz. 1.711, is still greater, but nearer to it than the former; the difference between the third and fifth terms, viz. 1.539, still approximates, as does that between the fourth and sixth, viz. 1.385; and indeed by continuing this series only for two terms longer, the difference will become smaller than the ratio. It is not worth while, however, to seek for series of this kind, as the present proposition will now be sufficiently intelligible without any farther illustration.

11. If quantities be arranged according to the order of their magnitudes, and if any two successive proportions of these be equal, the three successive terms which constitute them will also be equal. Thus, if the two quantities 12 and 8 constitute the proportion $\frac{12}{8}$, and each of them be lessened by 6, the half of 12, we have the proportion $\frac{6}{2}$; which is more than double the original proportion; for $\frac{12}{8} = 3$, and $\frac{6}{2} \times \frac{1}{2} = \frac{3}{1} = 3$.

12. When quantities are placed in the order of their magnitudes, if the intermediate magnitudes lying between any two terms be not among the mean proportion-

nals which can be interposed betwixt these two terms, then these intermediates will not divide the proportion of those two terms into commensurable proportions. Thus in the magnitudes 343 : 216 : 125 : 64 : 27 : 8, neither of the two intermediate terms 125 and 64 are mean proportionals betwixt 27 and 216, nor do they divide the proportion betwixt these into commensurable parts.

13. All the proportions taken in order, which are between expressible terms that are in arithmetical proportion, are incommensurable to one another; as between 8, 13, and 18.

14. When quantities are placed in the order of their magnitude, if the difference between the two greatest be made the measure of their proportion, the difference between any two others will be less than the measure of their proportion; and if the difference between the two least terms be made the measure of their proportion, the differences of the rest will be greater than the measure of the proportion between their terms.

15. If the measure of proportion between the greatest exceed their difference, then the proportion of this measure to the difference will be less than that of a following measure to the difference of its terms; because proportionals have the same ratio.

16. If three equidifferent quantities are taken in order, the proportion between the extremes is more than double that betwixt the two greater terms. Hence it follows, that half the proportion of the extremes is greater than the proportion between the greatest terms, but less than the proportion of the two least.

17. If two quantities constitute a proportion, and each be lessened by half the greater, the remainder will constitute a proportion more than double the former.

18. If 1000 numbers follow one another in the natural order, 1000, 999, 998, &c. and by continual multiplication and extraction of the square root we find mean proportionals, and thus *bisect*, as it is called, the ratio between the two greatest, so that the parts into which the ratio is divided become ultimately smaller than the excess of proportion betwixt the next two over the former (for 998 bears a greater proportion to 999 than 999 bears to 1000); the measure of this very small part or element of the proportion may be supposed to be the difference between 1000 and that mean proportional which is the other term of the element. Thus, for the sake of an easy explanation, let us suppose the numbers to be 10, 9, 8, &c. the ratio of 9 to 10 is 1.11, that of 9 to 8 is 1.125, the difference between which is .014, which we may call the elementary part of the ratios. By six extractions of the square root we have the mean proportional 9.985, &c. differing from 10 by no more than .015, which is very near the element just mentioned. The number of parts into which the ratio is thus divided is expressed by the 6th power of 2 or 64. Dividing therefore the ratio between 9 and 10 or 1.11 by 64, we have .017 for the elementary part thus obtained; which near coincidence with the real element, and the difference between 10 and the mean proportional itself, shews that in large numbers we may take the difference between the mean proportional and greatest term for the elementary part without any sensible error.

Suppose now, that the proportion between 1000

Construc-
tion of
Logarithms

and 998 be divided into twice the number of parts that the former was, it will be equally plain that the difference betwixt 1000 and the next mean proportional will be the measure of that element. Proceeding in like manner with the other numbers 1000 and 997, 1000 and 996, &c. it is evident, that by dividing into a proper number of parts, all the elements will be reduced to an equal degree of *fineness*, if we may so call it, and in calculations may be made use of without any fear of error.

19. The number of elementary parts being thus known which are contained in any proportion, it will be easy to find the ratios between those numbers which are in continued proportion to the first term of the series. Thus, having found the proportion between 1000 and 900,

we know also that of 1000 to 810, and 729;
And from 1000 to 800, also 1000 to 640, and to 512;
And from 1000 to 700, also 1000 to 490, and to 343;
And from 1000 to 600, also 1000 to 360, and to 216;
And from 1000 to 500, also 1000 to 250, and to 125.

Corol. Hence arises the precept for squaring, cubing, &c.; as also for extracting the square root, cube root, &c. out of the first figures of numbers. For it will be, As the greatest number of the chiliad as a denominator, is to the number proposed as a numerator, so is this to the square of the fraction, and so is this to the cube.

20. *Prop.* The proportion of a number to the first, or 1000, being known; if there be two other numbers in the same proportion to each other, then the proportion of one of these to 1000 being known, there will also be known the proportion of the other to the same 1000.

Corol. 1. Hence from the 15 proportions mentioned in prop. 18. will be known 120 others below 1000, to the same 1000.

For so many are the proportions, equal to some one or other of the said 15, that are among the other integer numbers which are less than 1000.

Corol. 2. Hence arises the method of treating the Rule-of-Three, when 1000 is one of the given terms.

For this is effected by adding to, or subtracting from, each other, the measures of the two proportions of 1000 to each of the other two given numbers, according as 1000 is, or is not, the first term in the Rule-of-three.

21. *Prop.* When four numbers are proportional, the

Let there be the fine 99970.1490 of an arc;
Its defect below radius is 29.8510 the covers. and less than logarithm fine;
Add the excess of the secant 29.8599

Sum 59.7109

its half or 29.8555 greater than the logarithm.

Therefore the logarithm is between } 29.8510 and
29.8555.

Precept 2. The logarithm of the fine being found, you will also find nearly the logarithm of the round or integer number which is next less than your fine with a fraction, by adding that fractional excess to the logarithm of the said fine.

Thus the logarithm of the fine 99970.149 is found to be about 29.854; if now the logarithm of the round N^o 184.

first to the second as the third to the fourth, and the proportions of 1000 to each of the three former are known, there will also be known the proportion of 1000 to the fourth number.

Corol. 1. By this means other chiliads are added to the former.

Corol. 2. Hence arises the method of performing the Rule-of-three, when 1000 is not one of the terms. Namely, from the sum of the measures of the proportions of 1000 to the second and third, take that of 1000 to the first, and the remainder is the measure of the proportion of 1000 to the fourth term.

Definition. The measure of the proportion between 1000 and any less number, as before described, and expressed by a number, is set opposite to that less number in the chiliad, and is called its *logarithm*, that is, the number (*λογος*) indicating the proportion (*μερος*) which 1000 bears to that number, to which the logarithm is annexed.

22. *Prop.* If the first or greatest number be made the radius of a circle, or *sinus totus*; every less number considered as the cosine of some arc, has a logarithm greater than the versed sine of that arc, but less than the difference between the radius and secant of the arc; except only in the term next after the radius, or greatest term, the logarithm of which by the hypothesis is made equal to the versed sine.

That is, if CD be made the logarithm of AC, or the measure of the proportion of AC to AD; then the measure of the proportion of AB to AD, that is, the logarithm of AB, will be greater than BD, but less than EF. And this is the same as Napier's first rule in page 44.

23. *Prop.* The same things being supposed; the sum of the versed sine and excess of the secant over the radius, is greater than double the logarithm of the cosine of an arc.

Corol. The logarithm cosine is less than the arithmetic mean between the versed sine and the excess of the secant.

Precept 1. Any fine being found in the canon of fines, and its defect below radius to the excess of the secant above radius; then shall the logarithm of the fine be less than half that sum, but greater than the said defect or covered fine.

number 99970.000 be required, add 149 the fractional part of the fine to its logarithm, observing the point, thus, 29.854 }
149 } is the logarithm of the round number 999700.000 nearly.

the sum 30.003

24. *Prop.* Of three equidifferent quantities, the measure

Construc-
tion of
logarithms

Construc-
tion of
Logarithms

sure of the proportion between the two greater terms, with the measure of the proportion between the two less terms, will constitute a proportion which will be greater than the proportion of the two greater terms, but less than the proportion of the two least.

Thus if AB, AC, AD, be three quantities having the equal differences BC, CD; and if the measure of the proportion of AD, AC be cd, and that of AC, AB, be bc; then the proportion of cd to cb will be greater than the proportion of AC to AD, but less than the proportion of AB to AC.

25. Prop. The said proportion between the two measures is less than half the proportion between the extreme terms: that is, the proportion between bc, cd, is less than half the proportion between AB, AD.

Corol. Since therefore the arithmetical mean divides the proportion into unequal parts, of which the one is greater and the other less than half the whole; if it be enquired what proportion is between these proportions, the answer is, that it is a little less than the said half.

An example of finding nearly the limits, greater and less, to the measure of any proposed proportion.—It being known that the measure of the proportion between 1000 and 900 is 10536.05, required the measure of the proportion 900 to 800, where the terms 1000, 900, 800, have equal differences. Therefore as 9 to 10, so 10536.05 to 11706.72, which is less than 11778.30, the measure of the proportion 9 to 8. Again, as the mean proportional between 8 and 10 (which is 8.9442719) is to 10, so 10536.05 to 11779.66, which is greater than the measure of the proportion between 9 and 8.

Axiom. Every number denotes an expresseble quantity.

26. Prop. If the 1000 numbers, differing by 1, follow one another in the natural order, and there be taken any two adjacent numbers, as the terms of some proportion; the measure of this proportion will be to the measure of the proportion between the two greatest terms of the chiliad, in a proportion greater than that which the greatest term 1000 bears to the greater of the two terms first taken, but less than the proportion of 1000 to the less of the said two selected terms.

So of the 1000 numbers taking any two successive terms, as 501 and 500, the logarithm of the former being 69114.92, and of the latter 69314.72, the difference of which is 199.80. Wherefore by the definition, the measure of the proportion between 501 and 500 is 199.80. In like manner, because the logarithm of the greatest term 1000 is 0, and of the next 999 is 100.05, the difference of these logarithms, and the measure of the proportion between 1000 and 999, is 100.05. Couple now the greatest term 1000 with each of the selected terms 501 and 500; couple also the measure 199.80 with the measure 100.05; so shall

Vol. X. Part I.

the proportion between 199.80 and 100.05 be greater than the proportion between 1000 and 501, but less than the proportion between 1000 and 500.

Corol. 1. Any number below the first 1000 being proposed, as also its logarithm; the differences of any logarithms antecedent to that proposed, towards the beginning of the chiliad, are to the first logarithm (viz. that which is assigned to 999) in a greater proportion than 1000 to the number proposed; but of those which follow towards the left logarithm, they are to the same in a less proportion.

Corol. 2. By this means the places of the chiliad may easily be filled up, which have not yet had logarithms adapted to them by the former propositions.

27. Prop. The difference of two logarithms, adapted to two adjacent numbers, is to the difference of these numbers in a proportion greater than 1000 bears to the greater of those numbers, but less than that of 1000 to the less of the two numbers.

This 27th proposition is the same as Napier's second rule.

28. Prop. Having given two adjacent numbers of the 1000 natural numbers, with their logarithmic indices, or the measures of the proportions which those absolute or round numbers constitute with 1000 the greatest; the increments or differences of these logarithms will be to the logarithm of the small element of the proportions, as the secants of the arcs whose co-sines are the two absolute numbers is to the greatest number, or the radius of the circle: so that, however, of the said two secants, the less will have to the radius a less proportion than the proposed difference has to the first of all, but the greater will have a greater proportion, and so also will the mean proportional between the said secants have a greater proportion.

Thus if BC, CD be equal, also bd the logarithm of AB, and cd the logarithm of AC; then the proportion of bc to cd will be greater than the proportion of AG to AD, but less than that of AF to AD, and also less than that of the mean proportional between AF and AG to AD.

Corol. 1. The same obtains also when the two terms differ, not only by the unit of the small element, but by another unit which may be ten fold, a hundred fold, or a thousand fold of that.

Corol. 2. Hence the differences will be obtained sufficiently exact, especially when the absolute numbers are pretty large, by taking the arithmetical mean between two small secants, or (if you will be at the labour) by taking the geometrical mean between two larger secants, and then by continually adding the differences, the logarithms will be produced.

Corol. 3. Precept. Divide the radius by each term of the assigned proportion, and the arithmetical mean (or still nearer the geometrical mean) between the quotients will be the required increment, which being added to the logarithm of the greater term, will give the logarithm of the less term.

R

EXAMPLE.

EXAMPLE.

Let there be given the logarithm of 700, viz. 35667.4948, to find the logarithm to 699.
Here radius divided by 700 gives 1428571, &c.
and divided by 699 gives 1430672, &c.
the arithmetic mean is 142.962
which added to 35667.4948

gives the logarithm to 699 35810.4568

Corol. 4. Precept for the logarithms of sine.

The increment between the logarithms of two fines is thus found: find the geometrical mean between the cosecants, and divide it by the difference of the fines, the quotient will be the difference of the logarithms.

EXAMPLE.

o 1' fine 2909 cosec. 343774682
o 2 fine 5818 cosec. 171887319

diff. 2909 geom. mean 2428 nearly.

The quotient 80000 exceeds the required increment of the logarithms, because the secants are here too large.

Appendix. Nearly in the same manner it may be shown, that the second differences are in the duplicate proportion of the first, and the third in the duplicate of the second. Thus, for instance, in the beginning of the logarithms, the first difference is 100.00000, viz. equal to the difference of the numbers 100000.00000 and 99900.00000; the second, or difference of the differences, 10000; the third 20. Again, after arriving at the number 50000.00000, the logarithms have for a difference 200.00000, which is to the first difference as the number 100000.00000 to 50000.00000; but the second difference is 40000, in which 10000 is contained four times; and the third 248, in which 20 is contained sixteen times. But since, in treating of new matters, we labour under the want of proper words, wherefore, lest we should become too obscure, the demonstration is omitted untried.

29. Prop. No number expresses exactly the measure of the proportion between two of the 1000 numbers constituted by the foregoing method.

30. Prop. If the measures of all proportions be expressed by numbers or logarithms; all proportions will not have assigned to them their due portion of measure, to the utmost accuracy.

31. Prop. If to the number 1000, the greatest of the chiliad, be referred others that are greater than it, and the logarithm of 1000 be made 0, the logarithms belonging to those greater numbers will be negative.

This concludes the first or scientific part of the work; the principles of which Kepler applies, in the second part, to the actual construction of the first 1000 logarithms, which is pretty minutely described. This part is intitled *A very compendious method of constructing the Chiliad of Logarithms*: and it is not improperly so called, the method being very concise and easy. The fundamental principles are briefly these: That at the beginning of the logarithms, their increments or differences are equal to those of the natural numbers: that the natural numbers may be considered as the decreasing cosines of increasing arcs: and that the secants of those arcs at the beginning have the same differences as the cosines, and therefore the same differences as the logarithms. Then, since the secants are the reciprocals of the cosines, by these principles and the third corol. to the twenty-eighth proposition, he establishes the fol-

lowing method of constituting the 100 first or smallest logarithms to the 100 largest numbers, 1000, 999, 998, 997, &c. to 900, viz. Divide the radius 1000, increased with seven ciphers, by each of these numbers separately, disposing the quotients in a table, and they will be the secants of those arcs which have the divisors for their cosines; continuing the division to the 8th figure, as it is in that place only that the arithmetical and geometrical means differ. Then, by adding successively the arithmetical means between every two successive secants, the sums will be the series of logarithms. Or, by adding continually every two secants, the successive sums will be the series of the double logarithms.

Besides these 100 logarithms thus constructed, he constitutes two others by continual bisection or extractions of the square root, after the manner described in the second postulate. And first he finds the logarithm which measures the proportion between 100000.00 and 97656.25, which latter term is the third proportional to 1024 and 1000, each with two cyphers; and this is effected by means of twenty-four continual extractions of the square root, determining the greatest term of each of twenty-four classes of mean proportionals; then the difference between the greatest of these means and the first or whole number 1000, with ciphers, being as often doubled, there arises 2371.6526 for the logarithm sought, which made negative is the logarithm of 1024. Secondly, the like process is repeated for the proportion between the numbers 1000 and 500, from which arises 69314.7193 for the logarithm of 500; which he also calls the logarithm of duplication, being the measure of the proportion of 2 to 1.

Then from the foregoing he derives all the other logarithms in the chiliad, beginning with those of the prime numbers 1, 2, 3, 5, 7, &c. in the first 100. And first, since 1024, 512, 256, 128, 64, 32, 16, 8, 4, 2, 1, are all in the continued proportion of 1000 to 500, therefore the proportion of 1024 to 1 is decuple of the proportion of 1000 to 500, and consequently the logarithm of 1 would be decuple of the logarithm of 500, if 0 were taken as the logarithm of 1024; but since the logarithm of 1024 is applied negatively, the logarithm of 1 must be diminished by as much: diminishing therefore 10 times the logarithm of 500, which is 693147.1928, by 2371.6526, the remainder 690775.5422 is the logarithm of 1, or of 100.00 what is set down in the table.

And because 1, 10, 100, Nos. Logarithms.
1000, are continued proportions, therefore the proportion of 1000 to 1 is triple of the proportion of 1000 to 100, and consequently 3 of the logarithm of 1 is to be put for the logarithm of 100, viz. 230258.5141, and this is also the logarithm of decuplication, or of the proportion of 10 to 1. And hence

Construc-
tion of
Logarithms

Construc-
tion of
Logarithms

hence multiplying this logarithm of 100 successively by 2, 3, 4, 5, 6, and 7, there arise the logarithms to the numbers in the decuple proportion, as under.

Also if the logarithm of duplication, or of the proportion of 2 to 1, be taken from the logarithm of 1, there will remain the logarithm of 2; and from the logarithm of 2 taking the logarithm of 10, there remains the logarithm of the proportion of 5 to 1; which taken from the logarithm of 1, there remains the logarithm of 5. See the margin.

For the logarithms of other prime numbers, he has recourse to those of some of the first or greatest century of numbers, before found, viz. of 999, 998, 997, &c. And first, taking 960, whose logarithm is 4082.2001; then by adding to this logarithm the logarithm of duplication, there will arise the several logarithms of all these numbers, which are in duplicate proportion continued from 960, namely 480, 240, 120, 60, 30, 15. Hence the logarithm of 30 taken from the logarithm of 10, leaves the logarithm of the proportion of 3 to 1; which taken from the logarithm of 1, leaves the logarithm of 3, viz. 5809.143106. And the double of this diminished by the logarithm of 1, gives 4710.530790 for the logarithm of 9.

Next, from the logarithm of 990, or $9 \times 10 \times 11$, which is 1005.0331, he finds the logarithm of 11; namely, subtract the sum of the logarithms of 9 and 10 from the sum of the logarithm of 990, and double the logarithm of 1, there remains 450986.0106 the logarithm of 11.

Again, from the logarithm of 980, or $2 \times 10 \times 7 \times 7$, which is 2020.2711, he finds 496184.5228 for the logarithm of 7.

And from 5129.3303 the logarithm of 950 or $5 \times 10 \times 19$, he finds 396331.6392 for the logarithm of 19.

In like manner the logarithm to 998 or $4 \times 13 \times 19$, gives the logarithm of 13; to 969 or $3 \times 17 \times 19$, gives the logarithm of 17; to 986 or $2 \times 17 \times 29$, gives the logarithm of 29; to 966 or $6 \times 7 \times 23$, gives the logarithm of 23; to 930 or $3 \times 10 \times 31$, gives the logarithm of 31.

And so on for all the primes below 100, and for many of the primes in the other centuries up to 900. After which he directs to find the logarithms of all numbers composed of these, by the proper addition and subtraction of their logarithms, namely, in finding the logarithm of the product of two numbers, from the sum of the logarithms of the two factors take the logarithm of 1, the remainder is the logarithm of the product. In this way he shows, that the logarithms of all numbers under 500 may be derived, except those of the following 36 numbers, namely 127, 149, 167, 173, 179, 211, 223, 251, 257, 263, 269, 271, 277, 281, 283, 293, 337, 347, 349, 353, 359, 367, 373, 379, 383, 389, 397, 401, 409, 419, 421, 431, 433, 439, 443, 449. Also, besides the composite numbers between 500 and 900, made up of the products of some numbers whose logarithms have been before determined, there will be 59 primes not composed of them; which with the 36 above mentioned make 95 num-

bers in all not composed of the products of any before them, and the logarithms of which he directs to be derived in this manner; namely, by considering the differences of the logarithms of the numbers interperled among them; then by that method by which were constituted the differences of the logarithms of the smallest 100 numbers in a continued series, we are to proceed here in the discontinued series, that is, by prop. 28th, coroll. 3d, and especially by the appendix to it, if it be rightly used, from whence those differences will be very easily supplied.

§ 3. Mr Briggs's Method.

THE methods principally made use of by this gentleman were published in Napier's posthumous work. Having supposed 0 to be the logarithm of 1, and 1 with any number of ciphers annexed, suppose 10 to be the logarithm of 10, this number is to be divided ten times by 5, which in a logarithmic number is equivalent to the extraction of the root of the fifth power; by which means he obtains the following numbers, viz. 2 with nine ciphers to it; 4 with eight ciphers; 8 with seven ciphers; 16 with six ciphers; 32 with five ciphers; 64 with four; 128000, 25600, 5120, and 1024. Dividing this last logarithm ten times by 2, we have a geometrical series of ten numbers; the first of which is 512, and the last 1. Thus 20 logarithms are obtained: but the labour of finding the numbers belonging to them is so excessive, that it is surprising how it could be undergone by any body. To obtain those corresponding to the first ten logarithms, the fifth root must be extracted ten times, and the square root as often, to obtain the numbers corresponding to the others. The power from which these extractions is made, must originally be 1, with a number of ciphers annexed. Other logarithms might be formed from these by adding them, and multiplying their corresponding numbers; but as this method, besides its excessive labour, would produce only an *antilogarithmic* canon like that of Mr Dodson already mentioned, other more easy and proper methods were thought of.

The next was by finding continually geometrical means, first between 10 and 1, and then between 10 and that mean, and so on, taking the arithmetical means between their corresponding logarithms. The operation is also facilitated by various properties of numbers and their logarithms, as that the products and quotients of numbers correspond to the sums and differences of their logarithms; that the powers and roots of numbers answer to the products and quotients of the logarithms by the index of the power or root. Thus having the logarithm of 2, we can have those of 4, 16, 256, &c. by multiplying the logarithms by 2, and squaring the numbers to as great an extent in that series as we please. If we have also that of 3, we can not only have those of 9, 81, 8561, &c. but of 6, 18, 27, and all possible products of the powers of 2 and 3 into one another, or into the numbers themselves. The following property may also be of use, viz. that if the logarithms of any two numbers are given, and each number be raised to the power denoted by the index of the other, the products will be equal. Thus,

Log.	0	1	2	3	4	5	6
Nat. numb.	1	2	4	8	16	32	64

Let the two numbers be 4 and 16; it is plain, that if

Confir-
mation of
Logarithms

we raise 4 to the fourth power and 16 to the square, the products will be the same; for $16 \times 16 = 256$, and $4 \times 4 = 16$; $16 \times 4 = 64$; and $64 \times 4 = 256$.

Another method mentioned by Mr Briggs depends upon this property, that the logarithm of any number in this scale is 1 less than the number of places or figures contained in that power of that number whose exponent is the logarithm of 10, at least as to integral numbers; for Mr Briggs has shown that they really differ by a fraction. To this Mr Hutton adds the following; viz. that of any two numbers, as the greater is to the less, so is the velocity of the increment or decrement of the logarithms at the greater; "that is (says he), in our modern notation, as $X : Y :: y : x$; where x and y are the fluxions of X and Y .

In the treatise written upon the construction of logarithms by Mr Briggs himself, he observes, that they may be constructed chiefly by the two methods already mentioned, concerning which he premises several lemmata concerning the powers of numbers and their indices, and how many places of figures are in the products of numbers. He observes, that these products will consist of as many figures as there are in both factors, unless the first figures in each factor be expressed in one figure only, which sometimes happens, and then there will commonly be one figure less in the product than in the two factors. He observes also, that if in any series of geometricals, we take two terms, and raise one to the power denoted by the index of the other, or any number raised to the power denoted by the logarithm of the other, the product will be equal to this latter number raised to the power denominated by the logarithm of the former. Hence, if one of the numbers be 10, whose logarithm is 1 with any number of cyphers, then any number raised to the power whose index is the logarithm of that number, that is, the logarithm of any number in this scale where 1 is the logarithm of 10, is the index of that power of 10, which is equal to the given number. But the index of any integral power of 10 is one less than the number of places of figures it contains. Thus the square of 10, or 100, contains three places of figures, which is more by one, than 2 the index of the power; 1000, the cube of 10 contains four places, which is one more than the index, 3, of the power. Hence as the number of places of the powers of 10 are always exactly one more than the indices of those powers, it follows that the places of figures in the powers of any other number which is no integral power of 10, will not always be exactly one less in number than the indices of the powers. From these two properties is deduced the following rule for finding the logarithms of many prime numbers.

Find the 10th, 100th, 1000th, or any other power of a number, suppose 2, with the number of places of figures in it, then that number of figures shall always exceed the logarithm of 2, although the excess will be constantly less than 1; whence by proceeding to very high powers we will at last be able to obtain the logarithm of the number to great exactness.

Thus, the logarithm of 2, found by other methods, is known to be 30102999566389, &c. The tenth power of 2 is 1024; which containing four places of figures, gives 4 for the logarithm of 2, which exceeds it, though not quite by 1. The 20th power of 2, consisting of the 10th power multiplied into itself, by

its number of places ought to give the logarithm of 4; and according to the rule already laid down, should contain eight places of figures: but by reason of the cipher which stands in the second place, it is easy to see that it must contain only seven; which therefore gives seven for the logarithm of four. The logarithm of 16 is then expressed by the number of places of figures in the product of the 20th power of 2 into itself; and is therefore denominated by 13. That of 256 is denoted by the 80th power of 2, containing 25 places of figures. The logarithm of 2, therefore, having been already expressed by the 10th power of 2, will be again expressed by the 100th power. Adding, therefore, the number of places contained in the 80th power, viz. 25 to 7, the number of places contained in the 20th, we have 32 for the next expression of that logarithm. On account of the cipher which stands in the second place of one of the factors, however, we must deduct one from the number; and thus we have 31 for the logarithm of 2, which is a considerable approximation. Proceeding in this manner, at the 100th power of 2, we have 302 for the logarithm of 2; at the 10,000th power we have 3011; at the 100,000th power, 30103; at the 1,000,000th, we have 301030; and at the 10,000,000th power, we obtain 3010300; which is as exact as is commonly expressed in the tables of logarithms; but by proceeding in the same manner we may have it to any degree of exactness we please. Thus, at the 100,000,000th power, we have 30103000; and at the 1,000,000,000th, the logarithm is 301029996, true to eight places of figures.

The only difficulty in this method is to find the number of places of figures in the different powers without multiplying them; but this may be determined by only multiplying the first five; or even the first three of the products will be sufficient to determine this; and the logarithms may thus be found with very great facility.

When the logarithms, however, are required to a very great degree of exactness, our author thinks that the method of mean proportionals is most eligible. This consists in finding a great number of mean proportionals betwixt 1 and the number proposed; that is, first extracting the square root of the number itself, then extracting the root of that root, &c. until the last root shall exceed 1 only by a very small decimal. Finding then the logarithm of this number by methods hereafter to be described, he multiplies it by the index of the power of 2, denoted by the number of extractions of the square root; and the result is the required logarithm of the given number. In this method, the number of decimal places contained in the last root ought to be double the number of true places required in the logarithm itself, and the first half of them ought to be cyphers, the integer being 1. To find out the first small number and its logarithm, our author begins with 10 and its logarithm 1; continually extracting the root of the former, and bisecting the latter, till he comes to the 54th root, and then finds, that at the 53d and 54th roots both natural numbers and logarithms bear the same proportion to each other, viz. that of 2 to 1. Thus,

Numbers.

Construc-
tion of
Logarithms

If now by continual extraction and bisection we find any other small number, it will then be, as 12781, &c. is to 5551, &c. so is that other small decimal to the correspondent significant figures of its logarithm. To avoid, however, the excessive labour of such long multiplications and divisions, he reduces this ratio to another, the antecedent of which is 1. Thus, as 12781, &c. is to 5551, &c. so is 1 with as many ciphers annexed as precede the logarithms above mentioned, viz. 15, with another unit annexed to a 4th number, which will be the significant figures of the logarithm of the third term. The proportions then will be 12781 &c. : 5551 &c. :: 1.00000, 00000, 00000, 1 : 43429, 9445190351804; this last number, with 17 ciphers prefixed, being the logarithm of the one immediately preceding it. Having therefore found by continual extraction any such small decimal as the above, multiply it by 4342, &c. and the product will be the corresponding logarithm of the last root.

Still, as the labour of so many extractions must be intolerably tedious, it became necessary to fall upon some contrivances to shorten such operations; and of these the following is an example.

Let the number of which we seek the logarithm be involved to such an height that the index of the power may be one, with either one or more ciphers next to it. Divide this power then by 1 with as many ciphers annexed as the power has significant figures after the first; or, supposing all the figures after the first to be decimals, the roots are extracted continually from this power, till the decimal becomes sufficiently small, as when the first 15 places are ciphers; then, multiplying the decimal by 43429, &c. we have the logarithm of this last root; which logarithm, multiplied by the like power of the number 2, gives the logarithm of the first number of which the extraction was begun. To this logarithm if we prefix 1, 2, 3, &c. according as this number was found by dividing the power by 10, 100, 1000, &c. and lastly, dividing the result by the index of that power, the quotient will be the required logarithm of the given prime number.

Thus to find by this method the logarithm of 2. Raise it first to the 10th power, which is 1024; then cutting off for decimals the last three figures, we continually extract the square root from 1,024 forty-seven times, which gives

1.00000, 00000, 00000, 16851, 60579, 53949, 77; the decimal part of which multiplied by 43429, &c. gives 0.00000, 00000, 00000, 07313, 55936, 90623, 9368 for its logarithm, which being continually doubled 47 times, or multiplied at once by the 47th power of 2, viz. 140737488355328, gives for the logarithm of the number 10240.01029, 99566, 39811, 95265, 27744; true to 17 or 18 places of decimals; then prefixing to this

number 3, because the division was made by 1000 (for cutting off the three places of decimals is the same as dividing by 1000), we have for the logarithm of 1024, 3.010299566, &c. as above. Lastly, dividing by 10, because 1024 is the 10th power of 2, we have the logarithm of 2 itself; viz. 0.30102, &c.

The involving of any number to a very high power is by no means a matter of such difficulty as might at first sight be imagined. A number multiplied by itself produces the *square*; the square multiplied by itself produces the *biquadrate*; the biquadrate multiplied by itself gives the eighth power, and the eighth power multiplied by the square produces the tenth. The tenth power multiplied by itself gives the 20th, and the 20th multiplied by itself the 40th. The eighth power divided by the original number gives the seventh; and the 40th power multiplied by the seventh gives the 47th power required.

The *differential* method of constructing logarithms was likewise invented by our author, and greatly shortens the labour of finding the mean proportionals. Mr Briggs, in the course of his calculations, had observed, that these proportionals, found by continual extraction of roots, gradually approach nearer and nearer to the halves of the preceding root; and that as many significant figures as there are cyphers before them, agree exactly in this proportion. Subtracting therefore each of these decimal parts, which he called A, or the first differences, from half the next preceding one, and by comparing together the remainders or second differences, called B, he found that the succeeding were always nearly equal to $\frac{1}{4}$ of the next preceding ones; then taking the difference between each second difference and $\frac{1}{4}$ of the preceding one, he found that these third differences, called C, were nearly in the continual ratio of 8 to 1; again taking the difference between each C and $\frac{1}{4}$ of the next preceding, he found that these fourth differences, called D, were nearly in the continual ratio of 16 to 1; and so on, the 5th (E), 6th (F), &c. differences, being nearly in the continual ratio of 32 to 1, of 64 to 1, &c.: these plain observations being made, they very naturally and clearly suggested to him the notion and method of constructing all the remaining numbers from the differences of a few of the first, found by extracting the roots in the usual way. This will evidently appear from the annexed specimen of a few of the first numbers in the last example for finding the logarithm of 6; where after the 9th number the rest are supposed to be constructed from the preceding differences of each, as here shown in the 10th and 11th. And it is evident that, in proceeding, the trouble will become always less and less; the differences gradually vanishing, till at last only the first differences remain. And that generally each less difference is shorter than the next greater, by as many places as there are cyphers at the beginning of the decimal in the number to be generated from the differences.

He then concludes this chapter with an ingenious, but not obvious, method of finding the differences B, C, D, E, &c. belonging to any number, as suppose the 9th, from that number itself, independent of any of the preceding 8th, 7th, 6th, 5th, &c.;

and it is this: Raise the decimal A to the 2d, 3d, 4th, 5th, &c. powers; then will the 2d (B), 3d (C), 4th (D), &c. differences be as here below, viz.

$$\begin{aligned}
 B &= \frac{1}{2}A^2, \\
 C &= \frac{1}{6}A^3 + \frac{1}{24}A^4, \\
 D &= \frac{1}{24}A^4 + \frac{1}{72}A^5 + \frac{1}{720}A^6 + \frac{1}{5040}A^7 + \\
 E &= \frac{1}{720}A^5 + \frac{1}{2520}A^6 + \frac{1}{15120}A^7 + \frac{1}{60480}A^8 + \frac{1}{271584}A^9 + \frac{1}{1105920}A^{10}, \\
 F &= \frac{1}{15120}A^6 + \frac{1}{86400}A^7 + \frac{1}{291600}A^8 + \frac{1}{834000}A^9 + \frac{1}{1953120}A^{10}, \\
 G &= \frac{1}{86400}A^7 + \frac{1}{252000}A^8 + \frac{1}{1147500}A^9 + \frac{1}{6837216}A^{10}, \\
 H &= \frac{1}{252000}A^8 + \frac{1}{1510176}A^9 + \frac{1}{7068450}A^{10}, \\
 I &= \frac{1}{1510176}A^9 + \frac{1}{5490240}A^{10} + \frac{1}{2558465}A^{11}, \\
 K &= \frac{1}{5490240}A^{10} + \frac{1}{2805527}A^{11}, \\
 &\text{&c.}
 \end{aligned}$$

Thus in the 9th number of the foregoing example, omitting the ciphers at the beginning of the decimals, we have

$$\begin{aligned}
 A &= 1,51164,65999,05672,95048,8 \\
 A^2 &= 2,28507,54433,06381,6726 \\
 A^3 &= 3,45422,65239,48546,2 \\
 A^4 &= 5,22156,97802,288 \\
 A^5 &= 7,89316,8205 \\
 A^6 &= 11,93168,1 \\
 &\text{&c.}
 \end{aligned}$$

Consequently

$$\begin{aligned}
 A^{\frac{1}{2}} &= 1,14253,77215,03190,8363 = B \\
 \frac{1}{2}A^{\frac{1}{2}} &= 1,72711,32619,74273 \\
 \frac{1}{6}A^{\frac{1}{2}} &= 65269,62225 \\
 \frac{1}{24}A^{\frac{1}{2}} &= 1,72711,97889,36498 = C \\
 \frac{1}{720}A^{\frac{1}{2}} &= 4,56887,35577 \\
 \frac{1}{2520}A^{\frac{1}{2}} &= 6,90652 \\
 \frac{1}{15120}A^{\frac{1}{2}} &= 5 \\
 \frac{1}{86400}A^{\frac{1}{2}} &= 4,56894,26234 = D
 \end{aligned}$$

$$\begin{aligned}
 2^{\frac{1}{2}}A^{\frac{1}{2}} &= 20,71957 \\
 7A^{\frac{1}{2}} &= 83 \\
 2^{\frac{1}{2}}A^{\frac{1}{2}} + 7A^{\frac{1}{2}} &= 20,72040 = E
 \end{aligned}$$

which agree with the like differences in the foregoing specimen.

§ 4. Of Curves related to Logarithms.

SEVERAL other ingenious methods and improvements are laid down by our author in his treatise upon this subject; but as all these were attended with great labour, mathematicians still continued their efforts to facilitate the work; and it was soon perceived that some curves had properties analogous to logarithms. Edmund Gunter, it has been said, first gave the idea of a curve, whose abscissas are in arithmetical progression, while the corresponding ordinates are in geometrical progression, or whose abscissas are the logarithms of their ordinates; but it is not noticed in any part of his writings. The same curve was afterwards considered

Construc-
tion of
Logarithms

Construc-
tion of
Logarithms

considered by others, and named the *logarithmic* or *logarithmic curve* by Huygens in his *Disquisitione de Causa Gravitationis*, where he enumerates all the principal properties of this curve, showing its analogy to logarithms. Many other learned men have also treated of its properties; particularly Le Seur and Jacquier in their comment on Newton's Principia; Dr John Kiell in the elegant little tract on logarithms subjoined to his edition of Euclid's Elements; and Francis Maferes, Esq; curi-ator baron of the exchequer, in his ingenious treatise on Trigonometry; in which books the doctrine of logarithms is copiously and learnedly treated, and their analogy to the logarithmic curve, &c. fully displayed. It is indeed rather extraordinary that this curve was not sooner announced to the public; since it results immediately from Baron Napier's manner of conceiving the generation of logarithms, by only supposing the lines which represent the natural numbers to be placed at right angles to that upon which the logarithms are taken. This curve greatly facilitates the conception of logarithms to the imagination, and affords an almost intuitive proof of the very important property of their fluxions, or very small increments, viz. that the fluxion of the number is to the fluxion of the logarithm, as the number is to the subtangent; as also of this property, that, if three numbers be taken very nearly equal, so that their ratios to each other may differ but a little from a ratio of equality; as for example, the 3 numbers 10,000,000, 10,000,001, 10,000,002, their differences will be very nearly proportional to the logarithms of the ratios of those numbers to each other: all which follows from the logarithmic arcs being very little different from their chords, when they are taken very small. And the constant subtangent of this curve is what was afterwards by Cotes called the *modulus* of the system of logarithms: and since, by the former of the two properties above mentioned, this subtangent is a fourth proportional to the fluxion of the number, the fluxion of the logarithm, and the number, this property afforded occasion to Mr Baron Maferes to give the following definition of the *modulus*, which is the same in effect as Cotes's, but more clearly expressed; namely, that it is the limit of the magnitude of a fourth proportional to these three quantities, viz. the difference of any two natural numbers that are very nearly equal to each other, either of the said numbers and the logarithm or measure of the ratio they have to each other. Or we may define the *modulus* to be the natural number at that part of the system of logarithms, where the fluxion of the number is equal to the fluxion of the logarithm, or where the numbers and logarithms have equal differences. And hence it follows, that the logarithms of equal numbers or of equal ratios, in different systems, are to one another as the *moduli* of those systems. Moreover, the ratio whose measure or logarithm is equal to the *modulus*, and thence by Cotes called the *ratio modularis*, is by calculation found to be the ratio of 2.718281828459, &c. to 1, or of 1 to .367879441171, &c.: the calculation of which number may be seen at full length in Mr Baron Maferes's treatise on the Principles of Life-annuities, p. 274 and 275.

The hyperbolic curve also afforded another source for developing and illustrating the properties and construction of logarithms. For the hyperbolic areas ly-

ing between the curve and one asymptote, when they are bounded by ordinates parallel to the other asymptote, are analogous to the logarithms of their abscissas or parts of the asymptote. And so also are the hyperbolic sectors; any sector bounded by an arc of the hyperbola and two radii being equal to the quadrilateral space bounded by the same arc, the two ordinates to either asymptote from the extremities of the arc and the part of the asymptote intercepted between them. And although Napier's logarithms are commonly said to be the same as hyperbolic logarithms, it is not to be understood that hyperbolas exhibit Napier's logarithms only, but indeed all other possible systems of logarithms whatever. For, like as the right-angled hyperbola, the side of whose square is inscribed at the vertex is 1, gives us Napier's logarithms; so any other system of logarithms is expressed by the hyperbola whose asymptotes form a certain oblique angle, the side of the rhombus inscribed at the vertex of the hyperbola in this case also being still 1, the same as the side of the square in the right-angled hyperbola. But the areas of the square and rhombus, and consequently the logarithms of any one and the same number or ratio, will differ according to the sine of the angle of the asymptotes. And the area of the square or rhombus, or any inscribed parallelogram, is also the same thing as what was by Cotes called the *modulus* of the system of logarithms; which modulus will therefore be expressed by the numerical measure of the sine of the angle formed by the asymptotes, to the radius 1; as that is the same with the number expressing the area of the said square or rhombus, the side being 1: which is another definition of the modulus to be added to those we before remarked above in treating of the logarithmic curve. And the evident reason of this is, that in the beginning of the generation of these areas from the vertex of the hyperbola, the nascent increment of the abscissa drawn into the altitude 1, is to the increment of the area, as radius is to the sine of the angle of the ordinate and abscissa, or of the asymptotes; and at the beginning of the logarithms, the nascent increment of the natural numbers is to the increment of the logarithms as 1 is to the modulus of the system. Hence we easily discover, that the angle formed by the asymptotes of the hyperbola, exhibiting Briggs's System of Logarithms, will be $25^{\circ} 44' 25''$; this being the angle whose sine is 0.4342944819 , &c. the modulus of this system.

Or indeed any one hyperbola, as has been remarked by Mr Baron Maferes, will express all possible systems of logarithms whatever; namely, if the square or rhombus inscribed at the vertex, or, which is the same thing, any parallelogram inscribed between the asymptotes and the curve at any other point, be expounded by the modulus of the system; or, which is the same, by expounding the area, intercepted between two ordinates which are to each other in the ratio of 10 to 1 , by the logarithm of that ratio in the proposed system.

As to the first remarks on the analogy between logarithms and the hyperbolic spaces; it having been shown by Gregory St Vincent, in his *Quadratura Circuli et Sectorum Coni*, published at Antwerp in 1647, that if one asymptote be divided into parts in geometrical progression, and from the points of division or-

dinated

Construc-
tion of
Logarithms

dinates be drawn parallel to the other asymptote, they will divide the space between the asymptote and curve into equal portions; from hence it was shown by Mercennus, that, by taking the continual sums of those parts, there would be obtained areas in arithmetical progression, adapted to abscissas in geometrical progression, and which therefore were analogous to a system of logarithms. And the same analogy was remarked and illustrated soon after by Huygens and many others, who show how to square the hyperbolic spaces by means of the logarithms. There are likewise many other geometrical figures which have properties analogous to logarithms; such as the equiangular spiral, the figures of the tangents and secants, &c.

§ 5. Mercator's Method.

THIS is purely arithmetical, and is founded upon the idea of logarithms already mentioned; viz. that they are the measures of ratios, and express the number of *ratiuncule* contained in any ratio into which it may be divided. Having shown then that these logarithms, or numbers of small ratios, or measures of ratios, may be all properly represented by numbers; and that of 1, or the ratio of equality, the logarithm or measure being always 0, the logarithm of 10, or the measure of the ratio of 10 to 1, is most conveniently represented by 1 with any number of ciphers; he then proceeds to show how the measures of all other ratios may be found from this last supposition. And he explains the principles by the two following examples.

First, to find the logarithm of 100·5, or to find how many *ratiuncule* are contained in the ratio of 100·5 to 1, the number of *ratiuncule* in the decuple ratio, or ratio of 10 to 1, being 10,000,000.

The given ratio 100·5 to 1 he first divides into its parts; namely, 100·5 to 100, 100 to 10, and 10 to 1; the last two of which being decuples, it follows that the characteristic will be 2, and it only remains to find how many parts of the next decuple belong to the first ratio of 100·5 to 100. Now if each term of this ratio be multiplied by itself, the products will be in the duplicate ratio of the first terms, or this last ratio will contain a double number of parts; and if these be multiplied by the first terms again, the ratio of the last products will contain three times the number of parts, and so on; the number of times of the first parts contained in the ratio of any like powers of the first terms, being always denoted by the exponent of the power. If therefore the first terms 100·5 and 100 be continually multiplied till the same powers of them have to each other a ratio whose measure is known; as suppose the decuple ratio 10 to 1, whose measure is 10,000,000: then the exponent of that power shows what multiple this measure 10,000,000 of the decuple ratio is of the required measure of the first ratio 100·5 to 100; and consequently dividing 10,000,000 by that exponent, the quotient is the measure of the ratio 100·5 to 100 sought. The operation for finding this he sets down as here follows; where the several multiplications are all performed in the contracted way by inverting the figures of the multiplier, and retaining only the first number of decimals in each product.

Nº 184.

Power.

1893406	-	-	-	128
6043981	-	-	-	128
3584985	-	-	-	256
5894853	-	-	-	256
12852116	-	-	-	512

This power being greater than the decuple of the like power of 100, which must always be 1 with ciphers, resume therefore the 256th power, and multiply it not by itself but by the next before it, viz. by the 128th, thus,

3584985	-	-	-	256
6043981	-	-	-	128
6787831	-	-	-	384
1106731	-	-	-	64
9340130	-	-	-	448
5303711	-	-	-	32
10956299	-	-	-	480

This power again exceeding the same power of 100 more than 10 times, he therefore draws the same power 448th not into the 32d but the next preceding, thus,

9340130	-	-	-	448
8603801	-	-	-	16
10115994	-	-	-	464

This being again too much, instead of the 16th draw it into the 8th or next preceding, thus,

9340130	-	-	-	448
6070401	-	-	-	8
9720329	-	-	-	456
0510201	-	-	-	4
9916193	-	-	-	460
5200101	-	-	-	2
10015603	-	-	-	462

Which

Construc-
tion of
Logarithms

Construc-
tion of
Logarithms

Which power again exceeds the limit: therefore

draw the 460th into the 1st, thus,	Power.
9916193	460
5001	1
9965774	461

Since therefore the 462d power of 1005 is greater, and the 461st power is less, than the decuple of the same power of 100; he finds that the ratio of 1005 to 100 is contained in the decuple more than 461 times, but less than 462 times. Again,

Since $\frac{460}{461}$ power is $\frac{9916193}{9965774}$ and the differences $\frac{461}{462}$ is $\frac{49581}{49829}$ nearly equal; therefore the proportional part which the exact power, or 1000000, exceeds the next less 9965774, will be easily and accurately found by the Golden Rule, thus:

The just power	10000000
and the next less	9965774
the difference	34226; then,

As 49829 the dif. between the next less and greater, : To 34226 the dif. between the next less and just, :: So is 10000 : to 6868, the decimal parts; and therefore the ratio of 1005 to 100, is 461.6868 times contained in the decuple or ratio of 10 to 1. Dividing now 1,0000000, the measure of the decuple ratio, by 461.6868, the quotient .00216597 is the measure of the ratio of 1005 to 100; which being added to 2, the measure of 100 to 1, the sum 2,00216597 is the measure of the ratio of 1005 to 1, that is, the log. of 1005 is 2,00216597.

In the same manner he next investigates the log. of 995, and finds it to be 1,99782307.

A few observations are then added, calculated to generalize the consideration of ratios, their magnitude and affections. It is here remarked, that he considers the magnitude of the ratio between two quantities as the same, whether the antecedent be the greater or the less of the two terms; so the magnitude of the ratio of 8 to 5 is the same as of 5 to 8; that is, by the magnitude of the ratio of either to the other is meant the number of *ratiunculae* between them, which will evidently be the same whether the greater or less term be the antecedent. And he farther remarks, that of different ratios, when we divide the greater term of each ratio by the less, that ratio is of the greater mass or magnitude which produces the greater quotient, *et vice versa*; although those quotients are not proportional to the masses or magnitudes of the ratios. But when he considers the ratio of a greater term to a less, or of a less to a greater, that is to say, the ratio of greater or less inequality, as abstracted from the magnitude of the ratio, he distinguishes it by the word *affection*, as much as to say greater or less affection, something in the manner of positive and negative quantities, or such as are affected with the signs + and — The remainder of this work he delivers in several propositions, as follows:

Prop. 1. In subtraction from each other two quantities of the same affection, to wit, both positive, or both negative; if the remainder be of the same affection with the two given, then is the quantity subtracted the less of the two, or expressed by the less number; but if the contrary, it is the greater.

Prop. 2. In any continued ratios, as $\frac{a}{a+b}$, $\frac{a+b}{a+2b}$

Vol. X. Part I.

$\frac{a+2b}{a+3b}$, &c. (by which is meant the ratios of a to $a+b$, $a+b$ to $a+2b$, $a+2b$ to $a+3b$, &c.) of equidifferent terms, the antecedent of each ratio being equal to the consequent of the next preceding one, and proceeding from less terms to greater; the measure of each ratio will be expressed by a greater quantity than that of the next following; and the same through all their orders of differences, namely, the 1st, 2d, 3d, &c. differences; but the contrary, when the terms of the ratios decrease from greater to less.

Prop. 3. In any continued ratios of equidifferent terms, if the 1st or least be a , the difference between the 1st and 2d b , and c , d , e , &c. the respective first term of their 2d, 3d, 4th, &c. differences; then shall the several quantities themselves be as in the annexed scheme; where each term is composed of the first term together with as many of the differences as it is distant from the first term, and to those differences joining, for coefficients, the numbers in the sloping or oblique lines contained in the annexed table of figurate numbers; in the same manner, he observes, as the same figurate numbers complete the powers raised from a binomial root, as had long before been taught by others. He also remarks, that this rule not only gives any one term, but also the sum of any number of successive terms from the beginning, making the 2d coefficient the 1st, the 3d the 2d, and so on; thus, the sum of the first 5 terms is $5a + 10b + 10c + 5d + e$.

1st term	-	a
2d	-	$a + b$
3d	-	$a + 2b + c$
4th	-	$a + 3b + 3c + d$
5th	-	$a + 4b + 6c + 4d + e$
&c.		&c.

In the 4th *prop.* it is shown, that if the terms decrease, proceeding from the greater to the less, the same theorems hold good, by only changing the sign of every other term, as below.

1st term	-	a
2d	-	$a - b$
3d	-	$a - 2b + c$
4th	-	$a - 3b + 3c - d$
5th	-	$a - 4b + 6c - 4d + e$
&c.		&c.

Prop. 6th and 7th. treat of the approximate multiplication and division of ratios, or, which is the same thing, the finding nearly any powers or any roots of a given fraction, in an easy manner. The theorem for raising

Con-
struction
of
Logarithms

raising any power, when reduced to a simpler form, is this, the m power of $\frac{a}{b}$, or $\frac{a}{b}$ is $\frac{s \mp md}{s \pm md}$ nearly, where s is $a + b$, and $d = a - b$, the sum and difference of the two numbers, and the upper or under signs take place according as $\frac{a}{b}$ is a proper or an improper fraction, that is, according as a is less or greater than b . And the theorem for extracting the m th root of $\frac{a}{b}$ is $\sqrt[m]{\frac{a}{b}}$ or $\frac{a}{b}$ is $\frac{ms \mp d}{ms \pm d}$ nearly; which latter rule is also the same as the former, as will be evident by substituting $\frac{1}{m}$ instead of m in the first theo-

rem. So that universally $\frac{a}{b}$ is $\frac{ms \mp md}{ms \pm md}$ nearly.

These theorems, however, are nearly true only in some certain cases, namely, when $\frac{a}{b}$ and $\frac{m}{n}$ do not differ

greatly from unity. And in the 7th *prop.* the author shows how to find nearly the error of the theorems.

In the 8th *prop.* it is shown, that the measures of ratios of equidifferent terms, are nearly reciprocally as the arithmetical means between the terms of each ratio. So of the ratios $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, the mean between the terms of the first ratio is 1, of the 2d $\frac{3}{4}$, of the 3d $\frac{1}{2}$, and the measures of the ratios are nearly as $\frac{1}{1}, \frac{1}{\frac{3}{4}}, \frac{1}{\frac{1}{2}}$.

From this property he proceeds, in the 9th *prop.* to find the measure of any ratio less than $\frac{2}{1}$, which has an equal difference (1) of terms. In the two examples mentioned near the beginning, our author found the logarithm or measure of the ratio, of $\frac{2}{1}$, to be 21769, and that of $\frac{100}{1}$, to be 21659, and therefore the sum 43429 is the logarithm of $\frac{200}{1}$, or $\frac{2}{1} \times \frac{100}{1}$, or the logarithm of $\frac{200}{1}$ is nearer 43430, as found by other more accurate computations.

Now, to find the logarithm of $\frac{2}{1}$, having the same difference of terms (1) with the former; it will be, by *prop.* 8. as 100,5 (the mean between 101 and 100): 100 (the mean between 99,5 and 100,5): 43430: 43421,3 the logarithm of $\frac{2}{1}$, or the difference between the logarithms of 100 and 101. But the logarithm of 100 is 2; therefore the logarithm of 101 is 2,0043213.—Again, to find the logarithm of 102, we must first find the logarithm of $\frac{102}{101}$; the mean between its terms being 101,5, therefore as 101,5: 100: 43430: 42788 the logarithm of $\frac{102}{101}$, or the difference of the logarithms of 101 and 102. But the logarithm of 101 was found above to be 2,0043213; therefore the logarithm of 102 is 2,0086500.—So that dividing continually 868596 (the double of 434298 the logarithm of $\frac{200}{1}$, or $\frac{2}{1} \times \frac{100}{1}$) by each number of the series 201, 203, 205, 207, &c. then add 2

$$\frac{a}{b} = .001, \frac{ac}{bb} = .000000005, \frac{ac^2}{b^3} = .000000000000025, \frac{ac^3}{b^4} = .000000000000000125,$$

$$\&c.; \text{ therefore } \frac{a}{b-c} = \frac{a}{b} + \frac{ac}{bb} + \frac{ac^2}{b^3} + \frac{ac^3}{b^4}, \&c. \text{ is } .001000005000025000125,$$

$$\text{In like manner, if } c = 1.5, \text{ then } \frac{a}{b+c} \text{ will be } .001000015000225003375;$$

$$\text{and if } c = 2.5, \text{ then } \frac{a}{b+c} \text{ will be } .001000025000625015625;$$

Con-
struction
of
Logarithms

to the 1st quotient, to the sum add the 2d quotient, and so on, adding always the next quotient to the last sum, the several sums will be the respective logarithms of the numbers in this series, 101, 102, 103, 104, &c.

The next, or *prop.* 10th, shows that, of two pair of continued ratios, whose terms have equal differences, the difference of the measures of the first two ratios is to the difference of the measures of the other two, as the square of the common term in the two latter is to that in the former, nearly. Thus, in the four ratios $\frac{a}{a+b}, \frac{a+b}{a+2b}, \frac{a+2b}{a+3b}, \frac{a+3b}{a+4b}$, as the measure of $\frac{a+2b}{a+b}$ (the difference of the first two, or the quotient of the two fractions): the measure of $\frac{a+3b}{a+2b}$ (the difference of the last two, or the quotient of the two fractions): $\frac{a+2b}{a+b}^2$: $\frac{a+3b}{a+2b}^2$, nearly.

In *prop.* 11. the author shows that similar properties take place among two sets of ratios, consisting each of 3 or 4, &c. continued numbers.

Prop. 12. shows, that of the powers of numbers in arithmetical progression, the orders of differences which become equal, are the second differences in the squares, the 3d differences in the cubes, the 4th differences in the 4th powers, &c. And from hence it is shown, how to construct all those powers by the continual addition of their differences: As had been long before more fully explained by Briggs.

In the next, or 13th *prop.* our author explains his compendious method of raising the tables of logarithms, showing how to construct the logarithms by adding only, from the properties contained in the 8th, 9th, and 12th propositions. For this purpose he

makes use of the quantity $\frac{a}{b-c}$, which by division he

resolves into this infinite series $\frac{a}{b} + \frac{ac}{bb} + \frac{ac^2}{b^3} + \frac{ac^3}{b^4}$ &c. (in *infin.*) Putting then $a = 100$ the arithmetical mean between the terms of the ratio $\frac{200}{1}$, $b = 100000$, and c successively equal to 0,5, 1,5, 2,5, &c. that is $b-c$ may be respectively equal to 99999,5, 99998,5, 99997,5, &c. the corresponding means between the terms of the ratios $\frac{200}{99999}, \frac{200}{99998}, \frac{200}{99997}$, &c. it

is evident that $\frac{a}{b-c}$ will be the quotient of the 2d term divided by the 1st in the proportions mentioned in the 8th and 9th propositions; and when each of these quotients are found, it remains then only to multiply them by the constant 3d term 43429, or rather 43429,8, of the proportion, to produce the logarithms of the ratios $\frac{200}{99999}, \frac{200}{99998}, \frac{200}{99997}$, &c. till $\frac{200}{1}$; then adding these continually to 4 the logarithm of 10000 the least number, or subtracting them from 5 the logarithm of the highest term 100000, there will result the logarithms of all the absolute numbers from 10000 to 100000. Now when c is 0,5, then

Construc-
tion of
Logarithms

&c. But instead of constructing all the values of $\frac{a}{b-c}$ in the usual way of raising the powers, he directs them to be found by addition only, as in the last proposition. Having thus found all the values of $\frac{a}{b-c}$, the author then

shows, that they may be drawn into the constant logarithm 43429 by addition only, by the help of the annexed table of the first 9 products of it.

The author then distinguishes which of the logarithms it may be proper to find in this way, and which from their component parts. Of these the logarithms of all even numbers need not be thus computed, being composed from the number 2; which cuts off one half of the numbers: neither are those numbers to be computed which end in 5, because 5 is one of their factors; these last are $\frac{1}{5}$ of the numbers; and the two together $\frac{4}{5} + \frac{1}{5}$ make $\frac{1}{2}$ of the whole: and of the other $\frac{1}{2}$, the

As 10048, the arithmetical mean between 10033 and 10063,
to 10018, the arithmetical mean between 10003 and 10033,
so 13006, the difference between the logarithms of 10003 and 10033,
to 12967, the difference between the logarithms of 10033 and 10063;

That is, 1st As $\left\{ \begin{array}{l} 10048 \\ 10078 \\ 10108 \end{array} \right\}$: 10018 : : 13006 : $\left\{ \begin{array}{l} 12967 \\ \&c. \end{array} \right\}$
Again, As $\left\{ \begin{array}{l} 10058 \\ 10088 \\ 10118 \end{array} \right\}$: 10028 : : 12992 : $\left\{ \begin{array}{l} 12953 \\ \&c. \end{array} \right\}$
And 3dly, As $\left\{ \begin{array}{l} 10068 \\ 10098 \\ \&c. \end{array} \right\}$: 10038 : : 12979 : $\left\{ \begin{array}{l} 12940 \\ \&c. \end{array} \right\}$

And with this our author concludes his compendium for constructing the tables of logarithms.

§ 6. Gregory's Method.

THIS is founded upon an analogy between a scale of logarithmic tangents and Wright's protraction of the nautical meridian line consisting of the sums of the secants. It is not known by whom this discovery was made; but, about 1645, it was published by Mr Henry Bond, who mentions this property in Norwood's Epitome of Navigation. The mathematical demonstration of it was first investigated by Mercator; who, with a view to make some advantage of his discovery, offered, in the Philosophical Transactions for June 4th 1666, to lay a wager with any one concerning it; but this proposal not being accepted, the demonstration was not published. Other mathematicians, however, soon found out the mystery; and in two years after, Dr Gregory published a demonstration, and from this and other similar properties he showed a method of computing the logarithmic sines and tangents by means of an infinite series. Several of these were invented by him, and the method of applying them laid down by himself and others; but Mr Hutton thinks that a shorter and better method than any they proposed

$\frac{1}{2}$ of them, or $\frac{1}{2}$ of the whole, are composed of 3; and hence $\frac{1}{2} + \frac{1}{2}$, or $\frac{1}{1}$ of the numbers, are made up of such as are composed of 2, 3, and 5. As to the other numbers which may be composed of 7, of 11, &c.; he recommends to find their logarithms in the general way, the same as if they were incomposites, as it is not worth while to separate them in so easy a mode of calculation. So that of the 90 chiliads of numbers from 10000 to 100000, only 24 chiliads are to be computed. Neither indeed are all of these to

be calculated from the foregoing series for $\frac{a}{b-c}$, but

only a few of them in that way, and the rest by the proportion in the 8th proposition. Thus, having computed the logarithms of 10003 and 10013, omitting 10023 as being divisible by 3, estimate the logarithms of 10033 and 10043, which are the 30th numbers from 10003 and 10013; and again, omitting 10053, a multiple of 3, find the logarithms of 10063 and 10073. Then by prop. 8.

might have been found by computing, by means of the series, only a few logarithms of small ratios, in which the terms of the series would have decreased by the powers of 10 or some greater number, the numerators of all the terms being unity, and their denominators the powers of 10 or some greater number, and then employing these few logarithms, so computed, to the finding of the logarithms of other and greater ratios by the easy operations of mere addition and subtraction. This might have been done for the logs. of the ratios of the first ten numbers, 2, 3, 4, 5, 6, 7, 8, 9, 10, and 11, to 1, in the following manner, communicated by Mr Baron Mafceus.—In the first place the logarithm of the ratio of 10 to 9, or of 1 to $\frac{9}{10}$, or of 1 to $1 - \frac{1}{10}$, is equal to the series $\frac{1}{10} + \frac{1}{2 \times 100} + \frac{1}{3 \times 1000} + \frac{1}{4 \times 10000} + \frac{1}{5 \times 100000} \&c.$ In like manner are easily found the logarithms of the ratios of 11 to 10; and then by the same series those of 121 to 120, and of 81 to 80, and of 2401 to 2400; in all which cases the series would converge still faster than in the two first cases. We may then proceed by mere addition and subtraction of logarithms, as follows.

$\text{Log. } \frac{1}{9} = \text{L. } \frac{1}{10} + \text{L. } \frac{1}{9}$	$\text{L. } \frac{1}{10} = \text{L. } \frac{1}{9}$	$\text{L. } \frac{8}{9} = \text{L. } \frac{8}{10} - \text{L. } \frac{2}{10}$
$\text{L. } \frac{1}{81} = 2\text{L. } \frac{1}{9}$	$\text{L. } \frac{1}{9} = 2\text{L. } \frac{1}{10}$	$\text{L. } \frac{7}{9} = \text{L. } \frac{7}{10}$
$\text{L. } \frac{1}{729} = \text{L. } \frac{1}{81} + \text{L. } \frac{8}{81}$	$\text{L. } \frac{1}{90} = \text{L. } \frac{1}{10} + \text{L. } \frac{1}{9}$	$\text{L. } \frac{2}{9} = \text{L. } \frac{2}{10}$
$\text{L. } \frac{1}{6561} = \text{L. } \frac{1}{729} - \text{L. } \frac{1}{1771}$	$\text{L. } \frac{1}{8} = 2\text{L. } \frac{1}{4}$	$\text{L. } \frac{1}{7} = \text{L. } \frac{1}{5} - \text{L. } \frac{1}{35}$

S 2

Having

Construc-
tion of
Logarithms

Construc-
tion of
Logarithms.

Having thus got the logarithm of the ratio of 2 to 1, or, in common language, the logarithm of 2, the logarithms of all sorts of even numbers may be derived

from those of the odd numbers which are their coefficients with 2 or its powers. We may then proceed as follows.

Construc-
tion of
Logarithms.

$$\begin{array}{l|l|l} \text{L. } 4 = 2\text{L. } 2, & \text{L. } 100 = 2\text{L. } 10, & \text{L. } 2401 = \text{L. } \frac{2401}{11} + \text{L. } 2400, \\ \text{L. } 10 = \text{L. } \frac{1}{2} + \text{L. } 4, & \text{L. } 8 = 3\text{L. } 2, & \text{L. } 7 = \frac{1}{2}\text{L. } 2401, \\ \text{L. } 9 = \text{L. } \frac{2}{3} + \text{L. } 4, & \text{L. } 24 = \text{L. } 8 + \text{L. } 3, & \text{L. } 11 = \text{L. } \frac{1}{2} + \text{L. } 9. \\ \text{L. } 3 = \frac{1}{2}\text{L. } 9, & \text{L. } 2400 = \text{L. } 100 + \text{L. } 24, & \text{L. } 6 = \text{L. } 2 + \text{L. } 3. \end{array}$$

Thus we have got the logarithms of 2, 3, 4, 5, 6, 7, 8, 9, 10, and 11. And this is upon the whole, perhaps, the best method of computing logarithms that can be taken.—This method of computing logarithms is very nearly the same with that of Sir Isaac Newton in his second letter to Mr Oldenburg, dated October 1676.

§ 7. Construction of Logarithms by Fluxions.

From the definition and description of logarithms given by Napier, and of which we have already taken notice, it appears that the fluxion of his, or the hyperbolic logarithm of any number, is a fourth proportional to that number, its logarithm and unity; or, which is the same, that it is equal to the fluxion of the number divided by the number: For the description shows that $21 : 2a$ or $1 : 21$ is the fluxion of $21 : 2a$,

which therefore is $= \frac{21}{21}$; but $2a$ is also equal to the fluxion of the logarithm A , &c. by the description; therefore the fluxion of the logarithm is equal to $\frac{21}{21}$, the fluxion of the quantity divided by the quantity itself.

The same thing appears again at art. 2. of of that little piece in the appendix to his *Constructio Logarithmorum*, intitled *Habitudoines Logarithmorum et suorum naturalium numerorum invicem*; where he observes, that as any greater quantity is to a less, so is the velocity of the increment or decrement of the logarithms at the place of the less quantity to that at the greater. Now this velocity of the increment or decrement of the logarithms being the same thing as their fluxions, that proportion is this $x : a :: \text{flux. log. } a : \text{flux. log. } x$; hence if $a = 1$, as at the beginning of the table of numbers, where the fluxion of the logs. is the index or characteristic c , which is also one in Napier's or the hyperbolic logarithms, and 43429, &c. in Briggs's, the same proportion becomes $x : 1 :: c : \text{flux. log. } x$; but the constant fluxion of the numbers is also 1, and therefore that proportion is also this $x : 1 :: \frac{cx}{x} =$ the

fluxion of the logarithm of x : and in the hyperbolic logarithms, where c is $= 1$, it becomes $\frac{x}{x} =$ the fluxion of Napier's or the hyperbolic logarithm of x . This same property has also been noticed by many other

authors since Napier's time. And the same or a similar property is evidently true in all the systems of logarithms whatever, namely, that the modulus of the system is to any number as the fluxion of its logarithm is to the fluxion of the number.

Now from this property, by means of the doctrine of fluxions, are derived other ways for making logarithms, which have been illustrated by many writers on this branch; as Craig, Jo. Bernoulli, and almost all the writers on fluxions. And this method chiefly consists in expanding the reciprocal of the given quantity in an infinite series, then multiplying each term by the fluxion of the said quantity, and lastly taking the fluents of the terms; by which there arises an infinite series of terms for the logarithm sought. So, to find the logarithm of any number N , put any compound quantity for N , as suppose $\frac{n+x}{n}$; then the flux-

of the log. or $\frac{N}{N}$ being $\frac{x}{n+x} = \frac{x}{n} \frac{nx}{nn} + \frac{x^2}{n^3} - \frac{x^3}{n^4}$, &c.

the fluents give log. of N or log. of $\frac{n+x}{n} = \frac{x}{n} \frac{x^2}{2n^3} + \frac{x^3}{3n^4} - \frac{x^4}{4n^5}$, &c. And writing $-x$ for x gives log.

$\frac{n-x}{n} = -\frac{x}{n} \frac{x^2}{2n^3} - \frac{x^3}{3n^4} - \frac{x^4}{4n^5}$, &c. Also, because $\frac{n}{n-x} = 1 + \frac{n+x}{n}$, or log. $\frac{n}{n-x} = 0 + \log. \frac{n+x}{n}$, we

have log. $\frac{n}{n+x} = -\frac{x}{n} \frac{x^2}{2n^3} - \frac{x^3}{3n^4} + \frac{x^4}{4n^5}$, &c. and log. $\frac{n}{n-x} = +\frac{x}{n} \frac{x^2}{2n^3} + \frac{x^3}{3n^4} + \frac{x^4}{4n^5}$, &c.

And by adding and subtracting any of these series to or from one another, and multiplying or dividing their corresponding numbers, various other series for logarithms may be found, converging much quicker than these do.

In like manner, by assuming quantities otherwise compounded for the value of N , various other forms of logarithmic series may be found by the same means.

§ 8. Mr Long's Method.

THIS method was published in the 339th number of the Philosophical Transactions; and is performed by means of a small table containing eight classes of logarithms, as follows.

Lo.	Nat. Num.	Log.	Nat. Num.	Log.	Nat. Num.	Log.	Nat. Num.
99	7,943282347	,009	1,020939484	,00009	1,000207254	,0000009	1,000002072

Here, because the logarithms in each class are the continual multiples 1, 2, 3, &c. of the lowest, it is evident that the natural numbers are so many scales of geometrical proportionals, the lowest being the common ratio, or the ascending numbers are the 1, 2, 3, &c. powers of the lowest, as expressed by the figures 1, 2, 3, &c. of their corresponding logarithms. Also the last number in the first, second, third, &c. class, is the 10th, 100th, 1000th, &c. root of 10; and any number in any class is the 10th power of the corresponding number in the next following class.

To find the logarithm of any number, as suppose of 2000, by this table: Look in the first class for the number next less than the first figure 2, and it is 1,995262315, against which is 3 for the first figure of the logarithm sought. Again, dividing 2, the number proposed, by 1,995262315, the number found in the table, the quotient is 1,002374467; which being looked for in the second class of the table, and finding neither its equal nor a less, 0 is therefore to be taken for the second figure of the logarithm; and the same quotient 1,002374467 being looked for in the third class, the next less is there found to be 1,002305238, against which is 1 for the third figure of the logarithm; and dividing the quotient 1,002374467 by the said next less number 1,002305238, the new quotient is 1,000069700; which being sought in the fourth class gives 0, but sought in the fifth class gives 2, which are the fourth and fifth figures of the logarithm sought: again, dividing the last quotient by 1,000046053, the next less number in the table, the quotient is 1,000023015, which gives 9 in the 6th class for the 6th figure of the logarithm sought: and again dividing the last quotient by 1,000020724, the next less number, the quotient is 1,000002291, the next less than which in the 7th class gives 9 for the 7th figure of the logarithm: and dividing the last quotient by 1,000002072, the quotient is 1,000000219, which gives 9 in the 8th class for the 8th figure of the logarithm: and again the last quotient 1,000000219 being divided by 1,000000207 the next less, the quotient 1,000000012 gives 5 in the same 8th class, when one figure is cut off, for the 9th figure of the logarithm sought. All

which figures collected together give 3,301029995 for Briggs's logarithm of 2000, the index 3 being supplied; which logarithm is true in the last figure.

To find the number answering to any given logarithm, as suppose to 3,3010300: omitting the characteristic, against the other figures 3, 0, 1, 0, 3, 0, 0, as in the first column in the margin, are the several numbers as in the second column, found from their respective 1st, 2d, 3d, &c.

classes; the effective numbers of which multiplied continually together, the last product is 2,000000019966, which, because the characteristic is three, gives 2000,000019966 or 2000 only for the required number answering to the given logarithm.

§ 9. Mr Hutton's Practical Rule for the Construction of Logarithms.

THE methods laid down in the above sections are abundantly sufficient to show the various principles upon which logarithms may be constructed; though there are still a variety of others which our limits will not admit of our inserting: The following rule is added from Mr Hutton's Treatise on the subject, for the sake of those who do not choose to enter deeply into these investigations.

Call x the sum of any number whose logarithm is sought, and the number next less by unity; divide $\cdot 8685889638$, &c. (or $2 \div 2,3025$, &c.) by x , and reserve the quotient; divide the reserved quotient by the square of x , and reserve this quotient; divide this last quotient also by the square of x , and again reserve this quotient; and thus proceed continually, dividing the last quotient by the square of x as long as division can be made. Then write these quotients orderly under one another, the first uppermost, and divide them respectively by the uneven numbers 1, 3, 5, 7, 9, 11, &c. as long as division can be made; that is, divide the 1st reserved quotient by 1, the 2d by 3, the 3d by 5, the 4th by 7, &c. Add all these last quotients together, and the sum will be the logarithm of $b+a$; and therefore to this logarithm add also the logarithm

Construc-
tion of
Logarithms

arithm of a the next less number, and the sum will be the required logarithm of b the number proposed.

Ex. 1. To find the Log of 2.—Here the next less number is 1, and $2+1=3=z$, whose square is 9. Then,

3)	868588964	1)	289529654	289529654
9)	289529654	3)	32169962	10723321
9)	32169962	5)	3574440	714888
9)	3574440	7)	397160	56737
9)	397160	9)	44129	4903
9)	44129	11)	4903	446
9)	4903	13)	545	42
9)	545	15)	61	4
9)	61			

Log. $\frac{1}{2}$ - .301029995

Add L. 1 - .00000000

Log of 2 - .301029995

Ex. 2. To find the log. of 3.—Here the next less number is 2, and $2+3=5=z$, whose square is 25, to divide by which always multiply by .04. Then

5)	868588964	1)	173717793	173717793
25)	173717793	3)	6948712	2316237
25)	6948712	5)	277948	55590
25)	277948	7)	11118	1588
25)	11118	9)	448	50
25)	448	11)	18	2
	18			

L. $\frac{1}{2}$ - .176091260

L. 2 add - .301029995

L. 3 - .477121255

Then because the sum of the logarithms of numbers gives the logarithm of their product, and the difference of the logarithms gives the logarithm of the quotient of the numbers, from the above two logarithms, and the logarithm of 10, which is 1, we may raise a great many logarithms, thus:

Ex. 3. Because $2 \times 2 = 4$, therefore

to L. 2 - .301029995

add L. 2 - .301029995

sum is L. 4 - .602059991

Ex. 4. Because $2 \times 3 = 6$, therefore

to L. 2 - .301029995

add L. 3 - .477121255

sum is L. 6 - .778151250

Ex. 5. Because $2^2 = 8$, therefore

L. 2 - .301029995

mult. by 2 - 3

gives L. 8 - .903089987

Ex. 6. Because $3^2 = 9$, therefore

L. 3 - .477121255

mult. by 2 - 2

gives L. 9 - .954242509

Ex. 7. Because $1^2 = 1$, therefore

from L. 10 - 1.000000000

take L. 2 - .301029995

leaves L. 5 - .698970004

Ex. 8. Because $12 = 3 \times 4$, therefore

to L. 3 - .477121255

add L. 4 - .602059991

gives L. 12 - 1.079181246

And thus by computing, by the general rule, the logarithms of the other prime numbers 7, 11, 13, 17, 19, 23, &c.: and then using composition and division, we may easily find as many logarithms as we please, or may speedily examine any logarithm in the table.

§ 10. Mr Thomas Atkinson of Ballifhannon's Method.

In any series of numbers in a geometrical progression, beginning from unity, as in the margin, the series is composed of a 0 1 2 3 set of continued proportionals, of 1 10 100 1000 which the member standing nearest to unity is the common ratio or rate of the proportion. If over or under these another series is placed, as in the example, of numbers in an arithmetical progression, beginning with nought, and whose common difference is unity, the members of this series are called *indexes*; for they serve to show how many successive multiplications have been made with the common rate to produce that member of the geometrical progression over which each of these indexes does severally stand.

This theory may be considered in another light: If the square root of 10 (that is, of the common rate) is found, it is a mean proportional between 1 and 10, and becomes a new common rate for a new set of continued proportionals, as in the margin. And if the 0 .5 1 1.5 2 2.5 half of unity, which in 1 3.16 10 31.6 100 316. the former case was the additional difference of the arithmetical progression, is made the additional difference of this new series, and noted as in the example, a new combination is formed of two series agreeing with the first in these remarkable properties, viz. If any two members of the geometrical progression are multiplied together, the sum of their corresponding indexes will become the index of their product; and conversely, if any of them is divided by any other, the difference of their indexes will be found to be the index of the quotient. This theory is indefinite; and repeated extractions may be made with any proposed number of decimals, and bisection made of the corresponding indexes, until one has no more number to work with; and each of the mean proportionals thus found between 1 and 10, will be found a member of every new geometrical progression formed by every smaller root; and consequently all the roots thus found, together with their corresponding indexes, have, in cases of multiplication or division, the same connection as has been just described.

Let those successive roots be found, and noted in the form of a table, and, in another column, let the corresponding indexes found by these directions be regularly

Contraction of Logarithms. larily noted, each opposite to its own roots. These indexes are commonly known by the denomination of *logarithms*; the roots themselves may be called *natural numbers*.

These roots are composed of natural numbers freedom or never wanted; but from them the logarithms of such as are of general use may be thus found.

Suppose 2 the proposed number, one must examine the table of roots; there he will find 3.16, &c. &c. the nearest to 2 of those which are greater; and 1.778, &c. &c. also nearest to it of those which are less. He

may make a division at his pleasure, either $\frac{3.16}{2}$ or $\frac{2}{1.77}$; yet let the choice fall on what will yield the

$\frac{2}{1.77} = 1.1246$, &c. &c. smallest quotient, and let the circumstances of the calculation be noted, as in the margin, for future direction. Here

.0000087837, &c. .0000038147 its logm0000057968 of the quotient.
.0000025175, its logm.

Thus knowing that 0.0000025175, or such like, is the logm. of the last quotient, one may have that of 2, if he will but call to mind the following circumstances.

In every case of division, if he has logarithms of quotient and divisor, he has also that of the dividend, by adding the two first together: if he has the logarithm of the dividend, and that of either the divisor or quotient, he may find that of the other; for he has only to subtract what he knows from the logarithm of the dividend, the remainder is what he wants: and lastly, that in every division he made, he took one number from the table of roots whose logarithm is known, being noted in the table, and which he made use of as his direction either as a dividend or a divisor: From these circumstances, one may, by the help of the logarithm just found, discover the logarithm of that number of the last division, whether it be dividend or divisor, which was the quotient of the preceding division; and thus, tracing his own work backwards by his notes from quotient to quotient, be they ever so few or ever so many, he will come at last by addition and subtraction to the logarithm of the proposed number.

By this method, the logarithm of any number within the compass of the table of roots may be found: if a greater is proposed, suppose 9495, it must be made 9.495, and its logarithm found; then it must be re-

— 3.301029995664 the logarithm of the fraction given.
7 the power to which it is to be raised.

— 19.107209969648 the logarithm of the answer.

This differs from the like work in whole numbers only in this, that, in multiplying the decimals, one has at last 2 to be carried from them to the whole numbers; this is to be considered as + 2, then— $3 \times 7 = -21$, and— $21 + 2 = -19$ to be noted the index of the answer. Extraction of the roots is only the converse of this. Suppose—19.107209969648 given, to find that root whose exponent number is 7.

$\frac{2}{1.77} = 1.1246$. With this quotient let the table be applied to as before, and 1.1246, &c. will be found to be between 1.154, &c. &c. and 1.074, &c. &c. and division to be made as in the example. In this manner one is to proceed with each successive quotient, till at length he has one in which the number of the initial decimal noughts is equal at least, if not greater than that of the significant figures. Here the work of division may be discontinued; and as it will rarely happen, that one will not have an additional initial nought for every division, the number cannot be great in calculations of a moderate extent. Having at last found a quotient such as was described, and supposing the number of decimals to be 10, one may readily find the logm. of that quotient thus:—Suppose the quotient 1.0000057968; he is to look into the table of roots for those noted with 5 initial decimal noughts, and from any one of these and its corresponding logm. state thus:

flored to the proposed form, and have a proper index noted before the decimals just found. How to do this is too well known to have occasion to mention it here.

The reason for finding the logarithm of the last quotient by the common proportion is this: He who has made a table of roots, will find, by inspection only, that as initial noughts come into the decimal parts of the roots, the significant figures just immediately following them do assume the form of a geometrical progression, descending, whose common rate or divisor is 2, as is just the case with the whole of the decimals of the corresponding logarithms; and that the number of the significant figures endowed with this property is generally equal to that of the initial noughts: so far as this, and no farther, the common proportion will hold between the significant figures of the decimals in the roots and the same number of places in the logarithms; and for this reason it was needed to continue the successive divisions till a quotient was found so circumstanced, that its logarithm could be found by the proportion.

The same gentleman hath also favoured us with the following new method

Of extracting Roots of Fractions by LOGARITHMS.

THE easiest way to explain this, is first to give an example of involving such numbers.

As 7 is the exponent number here, one may in his mind multiply it by 2 for a trial, as in common division; but the product = 14 being less than 19, must be rejected; then he may try it with 3, this yields 21 for a product. This 3 must be noted with a negative sign for the index of the new logarithm. Then, on comparing 19 with 21, the difference is

— 19.107209969648
— 3.301029995664

Explanation of the Table.

2. This 2 must be carried as 20 to the decimals, and one must from that carry on the division of the de-

cimals with 7 for a divisor, as is usually done in other cases.

Explanation of the Table.

Another EXAMPLE.

Suppose -1.4771212545 given, to extract the root of its 5th power.

-1.8954252109 the logarithm of the root.

For 5, the exponent of the root $\times 1$ is greater than the index of the given logarithm, and 4 is the remainder. Then -1 becomes the index of the logarithm of the root; and 4= the overplus, is to be carried as 40 to the decimals; and from that, division is to be made with 5 as a divisor for the rest of the work.

SECT. III. *Explanation and Use of the Table, with a general Account of the various Sciences to which Logarithms may be applied.*

§ 1. To find by the table the Logarithm of any number.

If the number be under 100, it is easily found in the first division at the head of the first page; if it be betwixt 100 and 1000, over against the number in the first column of the following pages, in the next column under 0 will be found the logarithm required. If the number be betwixt 1000 and 10000, the first three figures of the number are to be found in the column marked N° and the fourth figure at the top, and in the column under it, lineally against the first three figures, will be found the logarithm required, changing the index 2 into 3. The column marked Diff. and showing the common difference by which each of these columns increases, serves to find the logarithms of numbers beyond 10000. Thus,

To find the logarithm for a number greater than any in the common canon, but less than 10000000.—Cut off four figures on the left of the given number, and seek the logarithm in the table; add as many unites to the index as there are figures remaining on the right; subtract the logarithm found from the next following it in the table; then, as the difference of numbers in the canon is to the tabular distance of the logarithms answering to them, so are the remaining figures of the given number to the logarithmic difference; which, if it be added to the logarithm before found, the sum will be the logarithm required. Suppose v. gr. the logarithm of the number 92375 required. Cut off the four figures 9237, and to the characteristic of the logarithm corresponding to them, add an unit; then,

From the logarithm of the numb. $9238 = 3.965578$
Subtract logarithm. numb. $-9237 = 3.965531$

Remains tabular difference 47
Then $10 : 47 :: 5 : 23$

Now to the logarithm 4.965531

Add the difference found -23

The sum is the logarithm required. -4.965554

Or more briefly; find the logarithm of the first four figures as before; then multiply the common difference which stands against it by the remaining figures of the given number; from the product, cut off as many figures at the right hand as you multiplied by, and add the remainder to the logarithm before found, fitting it with a proper index. Thus $47 \times 5 = 235$; cut off 5 and add 23.

To find the logarithm of a fraction.—Subtract the logarithm of the numerator from that of the denominator, and to the remainder prefix the sign of subtraction. N° 184.

traction. Thus suppose it required to find the logarithm of the fraction $\frac{7}{3}$.

Logarithm of 7 = 0.845098

Logarithm of 3 = 0.477121

Logarithm of $\frac{7}{3} = -0.367977$

The reason of the rule is, that a fraction being the quotient of the numerator divided by the denominator, its logarithm must be the difference of the logarithms of those two; so that the numerator being subtracted from the denominator, the difference becomes negative. Stifelius observed, that the logarithms of a proper fraction must always be negative, if that of unity be 0; which is evident, a fraction being less than one.

Or, the logarithm of the denominator, though greater than that of the numerator, as in the case of a proper fraction, may be subtracted from it, regard being had to the sign of the index, which alone in that case is negative. Thus,

Log. of 3 = 0.477121

Log. of 7 = 0.845098

Log. of $\frac{7}{3} = 1.632023$ which produces the same effect in any operation as that before found, viz. -0.367977 , this being to be subtracted, and the other to be added.

Or again, the fraction may be reduced to a decimal, and its logarithm found; which differs from that of a whole number only in the index, which is to be negative.

For an improper fraction v. gr. $\frac{7}{3}$, its numerator being greater than its denominator, its logarithm is had by subtracting the logarithm of the latter from that of the former.

The logarithm of 9 = 0.9542425

Logarithm of 5 = 0.6989700

Logarithm $\frac{7}{3} = 0.2552725$

In the same manner may a logarithm of a mixed number, as $3\frac{2}{3}$, be found, it being first reduced into an improper fraction $\frac{11}{3}$.

Or, this improper fraction may be reduced to a mixed number, whose logarithm must be found as if it were wholly integral, and its index taken according to the integral part. We shall here observe, that the logarithms of whole numbers are added, subtracted, &c. according to the rules of these operations in decimal arithmetic; but with regard to the management of logarithms with negative indices, the same rules are to be observed as those given in algebra for like and unlike signs.

In addition, all the figures except the index, are reckoned positive, and therefore the figure to be carried to the index from the other part of the logarithm takes away so much from the negative index. Thus $1.8683326 + 3.698972 = 1.562298$. In subtraction, if either one or both of the logarithms have negative indices, you must change the sign of the index of the sub-

sub-

Explanation of the Table, &c.

subtrahend, after you have carried it to what may arise from the decimal part, and then add the indices: thus $1.562298 - 1.863326 = 3.698972$. In multiplication, what is carried from the product of the other parts of the logarithms must be subtracted from the product of the indices: thus $2.477121 \times 5 = 8.385605$. In division, if the divisor will exactly measure the index, proceed as in common arithmetick; e. g. $4.924782 \div 2 = 2.462391$. But if the divisor will not exactly measure the index, add units to the index, till you can exactly divide it, and carry these units to the next number: e. g. $8.385605 \div 5 = 2.477121$.

To find the number corresponding to any given logarithm.—If the logarithm be within the limits of the table, i. e. if its index does not exceed 3, then neglecting the index, look down in the column of logarithms under 0, for the two or three first figures of your given logarithm; and if you exactly find all the figures of the given logarithm in that column, you have the number corresponding at the left hand: But if you do not find your logarithm exactly in the column under 0, you must run through the other columns till you find it exactly, or till you obtain the next least logarithm; and in the column of numbers lineally against it, you have the first 3 figures of the number sought, to which join the figure over the column, where your logarithm or its next least was found, and you have the corresponding number, e. gr. the number answering to the logarithm 3.544812 is 3506.

If the index of this logarithm had been 1, then the two last figures of the number would have been decimal; with the index 0, its corresponding number would have been 3506; with 1, 3506; with 2, 03506, &c.

If the logarithm cannot be found exactly, take the next least, and make the difference between the given logarithm and the next least the numerator of a fraction whose denominator shall be the common difference, and add the fraction to the number found in the table.

To find the number corresponding to a logarithm greater than any in the table.—First, from the given logarithm, subtract the logarithm of 10, or 100, or 1000, or 10,000, till you have a logarithm that will come within the compass of the table; find the number corresponding to this, and multiply it by 10, or 100, or 1000, or 10,000, the product is the number required.

Suppose, for instance, the number corresponding to the logarithm 7.758982 be required: subtract the logarithm of the number 10,000, which is 4.0000000, from 7.758982; the remainder is 3.758982, the number corresponding to which is 5741 $\frac{1}{100}$: this multiplied by 10,000, the product is 5741100, the number required.

Otherwise seek the decimal member of the logarithm in the table, and if you can find it exactly, you have the four first figures of the number in the table, to which affix as many ciphers as the given index exceeds 3, and it is the number required. But if you cannot find the logarithm exactly, take the next least, and find the four first figures of the corresponding number; then take the difference betwixt the given logarithm and the next least, and annex to it as many ciphers as the index exceeds 3; then divide by the common dif-

ference, and affix the quotient to the four first figures, and you have the number required.

To find the number corresponding to a negative logarithm. To the given negative logarithm add the last logarithm of the table, or that of the number 10000; i. e. subtract the first from the second, and find the number corresponding to the remainder; this will be the numerator of the fraction, whose denominator will be 10000; v. gr. suppose it to be required to find the fraction corresponding to the negative logarithm

0.3679767, subtract this from
4.0000000

The remainder is — 3.6320233, the number corresponding to which is 4285 $\frac{1}{1000}$, the fraction sought therefore is $\frac{4285}{1000}$. The reason of the rule is, that as a fraction is the quotient, arising on the division of the numerator by the denominator, unity will be to the fraction as the denominator to the numerator; but as unity is to the fraction corresponding to the given negative logarithm, so is 10000 to the number corresponding to the remainder: therefore, if 10000 be taken for the denominator, the number will be the numerator of the fraction required.

The negative logarithm — 0.3679777 is equal to the logarithm 1.632023, and the number answering to it, found in the manner already directed, will be 4285 $\frac{1}{1000}$.

The sines, tangents, &c. of any arch are easily found: by seeking the degree at the top, if the arch be less than 45°, and the minutes at the side, beginning from the top, and by seeking the degree, &c. at the bottom, if the arch be greater than 45°. If a given logarithmic sine or tangent falls between those in the tables, then the corresponding degrees and minutes may be reckoned $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$, &c. minutes more than those belonging to the nearest less logarithm in the tables, according as its difference from the given one is $\frac{1}{2}$, or $\frac{1}{3}$, or $\frac{1}{4}$, &c. of the difference between the logarithm next greater and next less than the given log.

§ 2. Of the various Sciences to which Logarithms may be applied.

As these artificial numbers constitute a new species of arithmetic capable of performing every thing which can be done in the old way, it is plain that its use must be equally extensive, and that in every science in which common arithmetic can be useful, the logarithmical arithmetic must be much more so, by reason of its being more easily performed. Though the general principles of logarithmical arithmetic have been already laid down, we shall here, in order to render the subject still more plain, subjoin the following practical rules.

I. Multiplication by Logarithms.

Add together the logarithms of all the factors, and the sum is a logarithm, the natural number corresponding to which will be the product required.

Observing to add, to the sum of the affirmative indices, what is carried from the sum of the decimal parts of the logarithms.

And that the difference betwixt the affirmative and negative indices is to be taken for the index to the logarithm of the product.

Explanation of the Table, &c.

Division by *Ex. 1.* To multiply 23.14 by 5.062.
 Logarithms 23.14 its log. is 1.3643634
 5.062 its log. is 0.7043221

Product 117.1347 - 2.0686855
Ex. 2. To mult. 2.581926 by 3.457291.
 2.581926 its log. is 0.4119438
 3.457291 - 0.5387359

Prod. 8.92647 - 0.9506797
Ex. 3. To mult. 3.902, and 597.16, and .0314728
 all together.

3.902 its log. is 0.5912873
 597.16 - 2.7760907
 .0314728 - 2.4979353

Prod. 73.33533 - 1.8653133
 The 2 cancels the 2, and the 1 to carry from the decimals is set down.

Ex. 4. To mult. 35.86, and 2.1046,
 and 0.8372, and 0.0294 all together.
 35.86 its log. is 0.5546103
 2.1046 - 0.3231696
 0.8372 - 1.9228292
 0.0294 - 2.4683473

Prod. 1.857618 - 1.2689564
 Here the 2 to carry cancels the 2, and there remain the 7 to set down.

II. Division by Logarithms.

From the logarithm of the dividend subtract the logarithm of the divisor, the remainder is a logarithm whose corresponding number will be the quotient required.

But first observe to change the sign of the index of the logarithm of the divisor, viz. from negative to affirmative, or from affirmative to negative; then take the sum of the indices if they be of the same kind, or their difference when of different signs, with the sign of the greater, for the index to the logarithm of the quotient.

And when 1 is borrowed in the left-hand place of the decimal part of the logarithm, add it to the index of the logarithm of the divisor when that index is affirmative, but subtract it when negative; then let the index thus found be changed, and worked with as before.

Ex. 1. To divide 24163 by 4567.
 Divide 24163 its log. 4.3831509
 Divif. 4567 - 3.6596310

Quot. 5.290782 - 0.7235199

Ex. 2. To divide 37.149 by 523.76.
 Divid. 37.149 its log. 1.5699471
 Divif. 523.76 - 2.7191323

Quot. .07092752 - 2.8508148

Ex. 3. To divide .06314 by .007241.
 Divid. .06314 its log. 2.8003046
 Divif. .007241 - 3.8597985

Quot. 8.719792 - 0.9405061

Here 1 carried from the decimals to the 3 makes it become 2, which taken from the other 2, leaves 0 remaining.

Ex. 4. To divide .7438 by 12.9476.
 Divid. .7438 its log. 1.8714562
 Divif. 12.9476 - 1.1121893

Quot. .05744694 - 2.7592669

Here the 1 taken from the 1 makes it become 2 to set down.

III. The Rule of Three, or Proportion.

Add the logarithms of the 2d and 3d terms together, and from their sum subtract the logarithm of the 1st by the foregoing rules; the remainder will be the logarithm of the 4th term required.

Or in any compound proportion whatever, add together the logarithms of all the terms that are to be multiplied, and from that sum take the sum of the others; the remainder will be the logarithm of the term sought.

But instead of subtracting any logarithm, we may add its complement, and the result will be the same. By the complement is meant the logarithm of the reciprocal of the given number, or the remainder by taking the given logarithm from 0, or from 10, changing the radix from 0 to 10; the easiest method of doing which, is to begin at the left hand, and subtract each figure from 9, except the last significant figure on the right-hand, which must be subtracted from 10. But when the index is negative, add it to 9, and subtract the rest as before. And for every complement that is added, subtract 10 from the last sum of the indices.

Ex. 1. To find a 4th proportional to 72.34, and 2.519, and 357.4862.

As 72.34 - comp. log. 8.1406215
 To 2.519 - 0.4012282
 So 357.4862 - 2.5532592

To 12.44827 - 1.0951089

Ex. 2. To find a 3d proportional to 12.796 and 3.24718.

As 12.796 - comp. log. 8.8929258
 To 3.24718 - 0.5115064
 So 3.24718 - 0.5115064

To .8240216 - 1.9159386

Ex. 3. To find a number in proportion to .379145 as .85132 is to .0649.

As .0649 - comp. log. 1.11877553
 To .85132 - 1.9300928
 So .379145 - 1.5788054

To 4.973401 - 0.6966535

Ex. 4. If the interest of 100l. for a year or 365 days be 4.5l. what will be the interest of 279.25l. for 274 days?

As $\begin{cases} 100 \\ 365 \end{cases}$ comp. log. $\begin{cases} 8.0000000 \\ 7.4377071 \end{cases}$
 To 279.25 - 2.4459932
 274 - 2.4377506
 So 4.5 - 0.6532125

To 9.433296 - 0.9746634

Evolution
by Loga-
rithms.

IV. *Evolution, or raising of Powers.*

Multiply the logarithm of the number given by the proposed index of the power, and the product will be the logarithm of the power sought.

Note. In multiplying a logarithm with a negative index by any affirmative number, the product will be negative.---But what is to be carried from the decimal part of the logarithm will be affirmative.---Therefore the difference will be the index of the product; and is to be accounted of the same kind with the greater.

Ex. 1. To find the 2d power of 25791.

Root 25791 its log.	-	0.4114682
index	-	2
		<hr/> 0.8229364

Power 6561756 - - - 0.8229364

Ex. 2. To find the cube of 307146.

Root 307146 its log.	-	0.4873449
index	-	3
		<hr/> 1.4620347

Power 2897575 - - - 1.4620347

Ex. 3. To find the 4th power of 09163.

Root 09163 its log.	-	2.9620377
index	-	4
		<hr/> 11.8481508

Power 0000704938 - - - 11.8481508

Here 4 times the negative index being 8, and 3 to carry, the difference 5 is the index of the product.

Ex. 4. To find the 365th power of 10045.

Root 10045 its log	-	0.0019499
index	+	365
		<hr/> 0.70495

Power 5148888 - - - 0.7117135

V. *Evolution, or Extraction of Roots.*

Divide the logarithm of the power or given number by its index, and the quotient will be the logarithm of the root required.

Note. When the index of the logarithm is negative, and the divisor is not exactly contained in it without a remainder, increase it by such a number as will

make it exactly divisible; and carry the units borrowed, as so many tens, to the left-hand place of the decimal part of the logarithm; then divide the results by the index of the root.

Evolution
by Loga-
rithms.

Ex. 1. To find the square root of 365.

Power 365	-	-	2)25622929
Root 1910498	-	-	12811465

Ex. 2. To find the cube root of 12345.

Power 12345	-	-	10)40914911
Root 2311162	-	-	13638304

Ex. 3. To find the 10th root of 2.

Power 2	-	-	10)03010300
Root 1071773	-	-	03010300

Ex. 4. To find the 365th root of 1045.

Power 1045	-	-	365)00191163
Root 1000121	-	-	00000524

Ex. 5. To find the square root of 093.

Power 093	-	-	2)29684829
Root 304959	-	-	14842415

Here the divisor 2 is contained exactly once in 2 the negative index; therefore the index of the quotient is 1.

Ex. 6. To find the cube root of 00048.

Power	-	-	3)46812412
Root 07829735	-	-	28937471

Here the divisor 3 not being exactly contained in 4, augment it by 2, to make it become 6, in which the divisor is contained just 2 times; and the 2 borrowed being carried to the other figures 6, &c. makes 26812412, which divided by 3 gives 8937471.

In trigonometry, the use of logarithmical sines, tangents, &c. are used as well as the common arithmetical logarithms; and by using them according to the rules above laid down, the operations are shortened to a degree altogether incredible to persons unacquainted with this invention. With equal facility are the problems in astronomy and navigation solved by their means, as well as those of the higher geometry, fluxions, and in short every thing which requires deep and laborious calculation. For the particular application of them to the different sciences, see the articles NAVIGATION, TRIGONOMETRY, &c.

LOG

LOG

LOGARITHMIC CURVE. If on the line AN both ways ind- finitely extended, be taken AC, CE, EG, GI, IL, on the right hand; and also A, G, P, &c. on the left, all equal to one another: and if at the points P, G, A, C, E, G, I, L, be erected to the right line AN, the perpendiculars PS, G, A, B, C, D, E, F, G, H, I, K, L, M, which let be continually proportional, and represent numbers, viz. AB, 1; CD, 10; EF, 100, &c. then shall we have two progressions of lines, arithmetical and geometrical: for the lines AC, AE, AG, &c. are in arithmetical progression, or as 1, 2, 3, 4, 5, &c. and so represent the logarithms to which the geometrical lines AB, CD, EF, &c. do correspond. For since AG is triple of the first line AC, the number GH shall be in the third place from unity, if CD be in the first: so likewise shall LM be in the fifth place, since AL = 5 AC. If the extremities of the proportionals S, d, B, D, F, &c. be joined by right lines, the figures SBML will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

If the parts A, C, E, G, &c. be bisected in the points c, e, g, i, k, l, there be again raised the perpendiculars, cd, ef, gh, ik, lm, which are mean proportionals between AB, CD, EF, &c. then there will arise a new series of proportionals, whose terms, beginning from that which immediately follows

unity, are double of those in the first series, and the Logarithmic curve, difference of the terms is become less, and approach nearer to a ratio of equality than before. Likewise, in this new series, the right lines AL, Ae, express the distances of the terms LM, cd, from unity, viz. since AL is ten times greater than Ae, LM shall be the tenth term of the series from unity: and because Ae is three times greater than Ac, ef will be the third term of the series if cd be the first, and there shall be two mean proportionals between AB and ef, and between AB and LM there will be nine mean proportionals. And if the extremities of the lines B, d, F, f, B, &c. be joined by right lines, there will be a new polygon made, consisting of more but shorter sides than the last.

If, in this manner, mean proportionals be continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as to be greater than any given number, or to be infinite; and every side of the polygon so lessened, as to become less than any given right line; and consequently the polygon will be changed into a curve-lined figure; for any curve-lined figure may be conceived as a polygon, whose sides are infinitely small and infinite in number. A curve described after this manner is called logarithmical.

It is manifest from this description of the logarithmic curve, that all numbers at equal distances are continually

Logarithmic Lines.

tinually proportional. It is also plain, that if there be four numbers, AB, CD, IK, LM, such that the distance between the first and second be equal to the distance between the third and the fourth, let the distance from the second to the third be what it will, these numbers will be proportional. For because the distances AC, IL, are equal, AB shall be to the increment D, as IK is to the increment MT. Wherefore, by composition, AB : DC :: IK : ML. And, contrariwise, if four numbers be proportional, the distance between the first and second shall be equal to the distance between the third and fourth.

The distance between any two numbers is called the *logarithm of the ratio of those numbers*; and, indeed, doth not measure the ratio itself, but the number of terms in a given series of geometrical proportionals, proceeding from one number to another, and defines the number of equal ratios by the composition whereof the ratios of number is known.

LOGARITHMIC Lines. For many mechanical purposes it is convenient to have the logarithms of numbers laid down on scales, as well as the logarithmic lines and tangents; by which means, computations may be carried on by mere mensuration with compasses. Lines of this kind are always put on the common Gunter's scale; but as these instruments must be extended to a very great length, in order to contain any considerable quantity of numbers, it becomes an object of importance to shorten them. Such an improvement has been made by Mr William Nicholson, and published in the 77th volume of the Philosophical Transactions. The principles on which the construction of his instruments depends are as follow:

1. If two geometrical series of numbers, having the same common ratio, be placed in order with the terms opposite to each other, the ratio between any term in one series and its opposite in the other will be constant: Thus,

2 6 18 54 162, &c.

3 9 27 81 243, &c. Then,

2 3 6 9 18 27 54 81 162 243, &c.

where it is evident, that each of the terms in the upper series is exactly two-thirds of the corresponding one in the lower.

2. The ratio of any two terms in one series will be the same with that between those which have an equal distance in the other.

3. In all such geometrical series as have the same ratio, the property above-mentioned takes place, tho' we compare the terms of any series with those of another: Thus,

2 4 8 16 32 64, &c.

3 6 12 24 48 96, &c.

4 8 16 32 64 128, &c.

5 10 20 40 80 160, &c.; where it is

plain that 2, 4, 3, 6; also 2, 4, 4, 8, and 2, 4, 5, 10, &c. have the same ratio with that of each series.

4. If the differences of the logarithms of the numbers be laid in order upon equidistant parallel right lines, in such a manner that a right line drawn across the whole shall intersect it at divisions denoting numbers in geometrical progression; then, from the condition of the arrangement, and the property of this logarithmic line, it follows, 1st, That every right line so drawn will, by its intersections, indicate a geometrical series of numbers; 2^{dly}, That such series as are indi-

cated by these right lines will have the same common ratio; and, 3^{dly}, That the series thus indicated by two parallel right lines, supposed to move laterally, without changing either their mutual distance or parallelism to themselves, will have each the same ratio, and in all series indicated by such two lines, the ratio between an antecedent and consequent; the former taken upon one line, and the latter upon another, will be also the same.

The 1st of these propositions is proved in the following manner. Let the lines AB, CD, EF, represent parts of the logarithmic line arranged according to the proportion already mentioned; and let GH be a right line passing through the points *e, c, a*, denoting numbers in geometrical progression; then will any other line IK, drawn across the arrangement, likewise pass through three points *f, d, b*, in geometrical progression. From one of the points of intersection *f* in the last mentioned line IK, draw the line *fg* parallel to GH, and intersecting the arrangement in the points *i, b*; and the ratios of the numbers *e, f, c, i*, will be equal, as well as of *a, b*; because the intervals on the logarithmic line, or differences of the logarithms of those numbers, are equal. Again, the point *f*, the line *id*, and the line *hb*, are in arithmetical progression denoting the differences between the logarithms of the numbers themselves; whence the quotients of the numbers are in geometrical progression.

The 2^d proposition is proved in a similar manner. For as it was shown that the line *fg*, parallel to GH, passes through points of division denoting numbers in the same continued ratio as those indicated by the line GH; it may also be shown, that the line LM parallel to any other line IK, will pass through a series of points denoting numbers which have the same continued ratio with those indicated by the line IK, to which it is parallel.

The 3^d proposition arises from the parallelism of the lines to their former situation; by which means they indicate numbers in a geometrical series, having the same common ratio as before: their distance on the logarithmic line also remains unchanged; whence the differences between the logarithms of the opposite numbers, and of consequence their ratios, will always be constant.

5. Supposing now an antecedent and consequent to be given in any geometrical series, it will always be possible to find them, provided the line be of unlimited length. Drawing two parallel lines, then, through each of the numbers, and supposing the lines to move without changing their direction or parallel situation, they will continually describe new antecedents and consequents in the same geometrical series as before.

6. Though the logarithmic line contain no greater range of numbers than from 1 to 10, it will not be found necessary for the purposes of computation to repeat it. The only thing requisite is to have a slider or beam with two fixed points at the distance of the interval betwixt 1 and 10, and a moveable point be made to range betwixt them always to indicate the antecedent; then, if the consequent fixed point fall without the rule, the other fixed point will always denote the division on which it would have fallen had the rule been prolonged; and this contrivance may easily be adapted to any arrangement of parallel lines whatever. The arrangement of right lines, however, ought always to be disposed in such a manner as to occupy a right

Logarithmic Lines.

Plate CCLXXXIII fig. 11.

Logarithmic Lines.

right angled parallelogram, or the cross line already mentioned ought always to be at right angles to the length of the ruler.

Fig. 7. is a ruler consisting of ten parallel lines. Fig. 8. a beam-compass for measuring the intervals. B, A, C, are the parts which apply to the surface of the ruler; the middle one, A, being moveable sidewise in a groove in the piece DE, so as always to preserve its parallelism to the external pieces DC, which are fixed at a distance equal to the length of the ruler, and have their edges placed in such a manner as to form with the parallel lines which they intersect a ratio, which by composition is $\frac{1}{2}$; which in the present case requires them to be at right angles to the length. The piece DE is applied to the edge FG of the ruler. The edges or borders H, I, K, L, are more conveniently made of transparent horn, or tortoise-shell, than of any opaque matter.

In using this ruler, apply the edge of either B or C to the consequent, and slide the piece A to the antecedent; observing the difference between the numbers on the pieces denoting the lines they are found on; then, applying the same edge of A to any other antecedent, the other piece B or C will intersect a consequent in the same ratio upon that line, having the same situation with regard to the antecedent that the line of the former consequent had to its antecedent. But if B be the consequent piece, and fall without the ruler, the piece C will show the consequent one line lower; or if C, in like manner, fall without the ruler, then B will show the consequent one line higher. "It might be convenient (says Mr. Nicholson) for the purpose of computation, to make instruments of this kind with one hundred or more lines: but in the present instrument, the numbers on the pieces will answer the same purpose; for if a consequent fall upon a line at any given number of intervals without the ruler, it will be found on that line of the arrangement which occupies the same number of intervals reckoned inwards from the opposite edge of the ruler."

Fig. 9. is an instrument on the plan of a Gunter's scale of 28 $\frac{1}{2}$ inches long, invented by the late Mr. Robertson. There is a moveable piece AB in the slider GH, across which is drawn a fine line: the slider having also lines CD, EF, drawn across it at distances from each other equal to the length of the ruler AB. In using the instrument, the line CD or EF is to be placed at the consequent, and the line in AB at the antecedent: then, if the piece AB be placed at any other antecedent, the same line CD or EF will indicate its consequent in the same ratio taken the same way: that is, if the antecedent and consequent lie on the

Logarithmic Lines.

same side of the slider, all other antecedents and consequents in that ratio will be in the same manner; and the contrary if they do not. But if the consequent line fall without the rule, the other fixed line on the slider will show the consequent, but on the contrary side of the slider to that where it would else have been seen by means of the first consequent line.

Fig. 10. is a circular instrument equivalent to the former; consisting of three concentric circles engraved and graduated upon a plate of an inch and an half diameter. Two legs A and B proceed from the centre, having right-lined edges in the direction of radii; and are moveable either singly or together. In using the instrument, place one of the edges at the antecedent and the other at the consequent, and fix them at the angle. Move the two legs then together; and having placed the antecedent leg at any other number, the other will give the consequent one in the like position on the lines. If the line CD happen to lie between the legs, and B be the consequent leg, the number sought will be found one line farther from the centre than it would otherwise have been; and on the contrary, it will be found one line nearer in the like case, if A be the consequent leg. "This instrument (says Mr. Nicholson) differing from that represented fig. 7. only in its circular form, and the advantages resulting from that form, the lines must be taken to succeed each other in the same manner laterally; so that numbers which fall either within or without the arrangement of circles, will be found on such lines of the arrangement as would have occupied the vacant places if the succession of lines had been indefinitely repeated sidewise.

"I approve of this construction as superior to every other which has yet occurred to me, not only in point of convenience, but likewise in the probability of being better executed; because small arcs may be graduated with very great accuracy, by divisions transferred from a larger original. The instrument, fig. 7. may be contained conveniently in a circle of about four inches and an half diameter.

"The circular instrument is a combination of the Gunter's line and the sector, with the improvements here pointed out. The property of the sector may be useful in magnifying the differences of the logarithms in the upper parts of the line of sines, the middle of the tangents, and the beginning of the versed sines. It is even possible, as mathematicians will easily conceive, to draw spirals, on which graduations of parts, every where equal to each other, will show the ratios of those lines by moveable radii, similar to those in this instrument."

L O G I C.

LOGIC is the art of thinking and reasoning justly; or, it may be defined the science or history of the human mind, inasmuch as it traces the progress of our knowledge from our first and most simple conceptions through all their different combinations, and all those numerous deductions that result from variously comparing them one with another.

The precise business of logic therefore is, To explain

the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge. It lays open those errors and mistakes we are apt, through inattention, to run into; and teaches us how to distinguish between truth, and what only carries the appearance of it. By these means we grow acquainted with the nature and force of the understanding; see what things lie within its reach.

reach; where we may attain certainty and demonstration; and when we must be contented with probability.

This science is generally divided into four parts,

viz. *Perception, Judgement, Reasoning, and Method.* This division comprehends the whole history of the sensations and operations of the human mind.

PART I. OF PERCEPTION.

WE find ourselves surrounded with a variety of objects, which acting differently upon our senses, convey distinct impressions into the mind, and thereby rouse the attention and notice of the understanding. By reflecting too on what passes within us, we become sensible of the operations of our own minds, and attend to them as a new set of impressions. But in all this there is only bare *consciousness*. The mind, without proceeding any farther, takes notice of the impressions that are made upon it, and views things in order, as they present themselves one after another. This attention of the understanding to the object acting upon it, whereby it becomes sensible of the impressions they make, is called by logicians *perception*; and the notices themselves, as they exist in the mind, and are there treasured up to be the materials of thinking and knowledge, are distinguished by the name of *ideas*. In the article *METAPHYSICS* it shall be shown at large, how the mind, being furnished with ideas, contrives to diversify and enlarge its stock: we have here chiefly to consider the means of making known our thoughts to others; that we may not only understand how knowledge is acquired, but also in what manner it may be communicated with the greatest certainty and advantage.

CHAP. I. Of Words, considered as the Signs of our Ideas.

Words furnish the means of recording our own thoughts;

I. OUR ideas, though manifold and various, are nevertheless all within our own breasts, invisible to others, nor can of themselves be made appear. But God, designing us for society, and to have fellowship with those of our kind, has provided us with organs fitted to frame articulate sounds, and given us also a capacity of using those sounds as signs of internal conceptions. Hence spring words and language: for, having once pitched upon any sound to stand as the mark of an idea in the mind, custom by degrees establishes such a connection between them, that the appearance of the idea in the understanding always brings to our remembrance the sound or name by which it is expressed; as in like manner the hearing of the sound never fails to excite the idea for which it is made to stand. And thus it is easy to conceive how a man may record his own thoughts, and bring them again into view in any succeeding period of life. For this connection being once settled, as the same sounds will always serve to excite the same ideas; if he can but contrive to register his words in the order and disposition in which the present train of his thoughts present themselves to his imagination, it is evident he will be able to recal these thoughts at pleasure, and that too in the very manner of their first appearance. Accordingly we find, that the inventions of writing and printing, by enabling us to fix and perpetuate such

perishable things as sounds, have also furnished us with the means of giving a kind of permanency to the transactions of the mind, inasmuch that they may be in the same manner subjected to our review as any other objects of nature.

II. But, besides the ability of recording our own thoughts, there is this farther advantage in the use of external signs, that they enable us to communicate our thoughts to others, and also to receive information of what passes in their breasts. For any number of men, having agreed to establish the same sounds as signs of the same ideas, it is apparent that the repetition of these sounds must excite the like perceptions in each, and create a perfect correspondence of thoughts. When, for instance, any train of ideas succeeds one another in my mind, if the names by which I am wont to express them have been annexed by those with whom I converse to the very same set of ideas, nothing is more evident, than that, by repeating those names according to the tenor of my present conceptions, I shall raise in their minds the same course of thought as has taken possession of my own. For by barely attending to what passes within themselves upon hearing the sounds which I repeat, they will also become acquainted with the ideas in my understanding, and have them in a manner laid before their view. So that we here clearly perceive how a man may communicate his sentiments, knowledge, and discoveries to others, if the language in which he converses be extensive enough to mark all the ideas and transactions of his mind. But as this is not always the case, and men are often obliged to invent terms of their own to express new views and conceptions of things; it may be asked, how in these circumstances we can become acquainted with the thoughts of another, when he makes use of words, to which we have never annexed any ideas, and that of course can raise no perceptions in our minds? In order to unveil this mystery, and give some little insight into the foundation, growth, and improvement of language, the following observations will be found of considerable moment.

III. First, that no word can be to any man the sign of an idea, till that idea comes to have a real existence in his mind. For names, being only so far intelligible as they denote known internal conceptions; where they have none such to answer them, there by they are plainly sounds without signification, and of course convey no instruction or knowledge. But no sooner are the ideas to which they belong raised in the understanding, than, finding it easy to connect them with the established names, we can join in any agreement of this kind made by others, and thereby enjoy the benefit of their discoveries. The first thing therefore to be considered is, how these ideas may be conveyed into the mind; that being there, we may learn to connect

And of the mutual communication of knowledge from one man to another.

Simple ideas cannot be conveyed into the mind by words, or a description.

ness them with their appropriated sounds, and so become capable of understanding others when they make use of these sounds in laying open and communicating their thoughts. Now, to comprehend this distinctly, it will be necessary to attend to the division of our ideas into simple and complex, (see *METAPHYSICS*.) And first, as for our simple ideas; they can find no admission into the mind, but by the two original fountains of knowledge, sensation and reflection. If therefore any of these have as yet no being in the understanding, it is impossible by words or a description to excite them there. A man who had never felt the sensation of *heat*, could not be brought to comprehend that sensation by any thing we might say to explain it. If we would really produce the idea in him, it must be by applying the proper object to his senses, and bringing him within the influence of a hot body. When this is done, and experience has taught him the perception to which men have annexed the name *heat*, it then becomes to him the sign of that idea, and he thenceforth understands the meaning of the term, which, before, all the words in this world would not have been sufficient to convey into his mind. The case is the same in respect of light and colours. A man born blind, and thereby deprived of the only conveyance for the ideas of this class, can never be brought to understand the names by which they are expressed. The reason is plain: they stand for ideas that have no existence in his mind; and as the organ appropriated to their reception is wanting, all other contrivances are vain, nor can they by any force or description be raised in his imagination. But it is quite otherwise in our complex notions. For these being no more than certain combinations of simple ideas, put together in various forms; if the original ideas out of which the collections are made have already got admission into the understanding, and the names serving to express them are known; it will be easy, by enumerating the several ideas concerned in the composition, and marking the order and manner in which they are united, to raise any complex conception in the mind. Thus the idea answering to the word *rain-bow* may be readily excited in the imagination of another who has never seen the appearance itself, by barely describing the figure, largeness, position, and order of colours; if we suppose these several simple ideas, with their names, sufficiently known to him.

IV. And this leads to a second observation upon this subject, namely, That words standing for complex ideas are all definable, but those by which we denote simple ideas are not; for simple ideas being secondary perceptions, which have no other entrance into the mind than by sensation or reflection, can only be got by experience, from the several objects of nature, proper to produce those perceptions in us. Words indeed may very well serve to remind us of them, if they have already found admission into the understanding, and their connection with the established names is known; but they can never give them their original being and existence there. And hence it is, that when any one asks the meaning of a word denoting a simple idea, we pretend not to explain it to him by a definition, well knowing that to be impossible; but, supposing him already acquainted with the idea, and only ignorant of the name by which it is called, we either men-

tion it to him by some other name with which we presume he knows its connection, or appeal to the object where the idea itself is found. Thus, were any one to ask the meaning of the word *white*, we should tell him it stood for the same idea as *albus* in Latin, or *blanc* in French; or, if we thought him a stranger to these languages, we might appeal to an object producing the idea, by saying it denoted the colour we observe in *snow* or *milk*. But this is by no means a definition of the word, exciting a new idea in his understanding; but merely a contrivance to remind him of a known idea, and teach him its connection with the established name. For if the ideas after which he inquires have never yet been raised in his mind; as suppose one who had seen no other colours than *black* and *white*, should ask the meaning of the word *scarlet*; it is easy to perceive, that it would be no more possible to make him comprehend it by words, or a definition, than to introduce the same perception into the imagination of a man born blind. The only method in this case is, to present some object, by looking at which the perception itself may be excited; and thus he will learn both the name and the idea together.

V. But how comes it to pass that men agree in the names of their simple ideas, seeing they cannot view the perceptions in one another's minds, nor make known these perceptions by words to others? The effect is produced by experience and observation. Thus finding, for instance, that the name of *heat* is annexed to that sensation which men feel when they approach the fire, I make it also the sign of the sensation excited in me by such an approach, nor have any doubt but it denotes the same perception in my mind as in theirs. For we are naturally led to imagine, that the same objects operate alike upon the organs of the human body, and produce an uniformity of sensations. No man fancies, that the idea raised in him by the taste of *sugar*, and which he calls *sweetness*, differs from that excited in another by the like means; or that *wormwood*, to whose relish he has given the epithet *bitter*, produces in another the sensation which he denotes by the word *sweet*. Presuming therefore upon this conformity of perceptions, when they arise from the same objects, we easily agree as to the names of our simple ideas: and if at any time, by a more narrow scrutiny into things, new ideas of this class come in our way, which we choose to express by terms of our own invention; these names are explained, not by a definition, but by referring to the objects whence the ideas themselves may be obtained.

VI. Being in this manner furnished with simple ideas, and the names by which they are expressed; the meaning of terms that stand for complex ideas is easily got, because the ideas themselves answering to these terms may be conveyed into the mind by definitions. For our complex notions are only certain combinations of simple ideas. When therefore these are enumerated, and the manner in which they are united into one conception explained, nothing more is wanting to raise that conception in the understanding; and thus the term denoting it comes of course to be understood. And here it is worth while to reflect a little upon the wise contrivance of nature, in thus furnishing us with the very aptest means of communicating our thoughts. For were it not so ordered, that

5
Experience and observation bring men to an agreement in the names of simple ideas.

6
The conveyance of complex ideas by definitions, a wise contrivance in nature;

4
The names of complex ideas definable, those of simple ideas not.

that we could thus convey our complex ideas from one to another by definitions, it would in many cases be impossible to make them known at all. This is apparent in those ideas which are the proper work of the mind. For as they exist only in the understanding, and have no real objects in nature in conformity to which they are framed; if we could not make them known by description, they must lie for ever hid within our own breasts, and be confined to the narrow acquaintance of a single mind. All the fine scenes that arise from time to time in the poet's fancy, and by his lively painting give such entertainment to his readers; were he destitute of this faculty of laying them open to the view of others by words and description, could not extend their influence beyond his own imagination, or give joy to any but the original inventor.

7
And of great avail towards the improvement of knowledge

VII. There is this farther advantage in the ability we enjoy of communicating our complex notions by definitions; that as these make by far the largest class of our ideas, and most frequently occur in the progress and improvement of knowledge, so they are by these means imparted with the greatest readiness, than which nothing would tend more to the increase and spreading of science: for a definition is soon perused; and if the terms of it are well understood, the idea itself finds an easy admission into the mind. Whereas in simple perceptions, where we are referred to the objects producing them, if these cannot be come at, as is sometimes the case, the names by which they are expressed must remain empty sounds. But new ideas of this class occurring very rarely in the sciences, they seldom create any great obstruction. It is otherwise with our complex notions; for every step we take leading us into new combinations and views of things, it becomes necessary to explain these to others, before they can be made acquainted with our discoveries: and as the manner of definitions is easy, requiring no apparatus but that of words, which are always ready, and at hand; hence we can with the less difficulty remove such obstacles as might arise from terms of our own invention, when they are made to stand for new complex ideas suggested to the mind by some present train of thinking. And thus at last we are let into the mystery hinted at in the beginning of this chapter, viz. how we may become acquainted with the thoughts of another, when he makes use of words to which we have as yet joined no ideas. The answer is obvious from what has been already said. If the terms denote simple perceptions, he must refer us to these objects of nature whence the perceptions themselves are to be obtained; but, if they stand for complex ideas, their meaning may be explained by a definition.

CHAP. II. Of Definitions.

8
Definition defined.

I. A Definition is the unfolding of some conception of the mind, answering to the word or term made use of as the sign of it. Now as, in exhibiting any idea to another, it is necessary that the description be such as may excite that precise idea in his mind; hence it is plain that definitions, properly speaking, are not arbitrary, but confined to the representing of certain determinate settled notions, such namely as are annexed by the speaker or writer to the words he uses. As never-

N° 185.

theless it is universally allowed that the signification of words is perfectly voluntary, and not the effect of any natural and necessary connection between them and the ideas for which they stand; some may perhaps wonder why definitions are not so too. In order therefore to unravel this difficulty, and show distinctly what is and what is not arbitrary in speech, we must carefully distinguish between the connection of our words and ideas, and the unfolding of the ideas themselves.

II. First, as to the connection of our words and ideas; this, it is plain, is a purely arbitrary institution. When, for instance, we have in our minds the idea of any particular species of metals, the calling it by the name *gold* is an effect of the voluntary choice of men speaking the same language, and not of any peculiar aptness in that sound to express that idea. Other nations we find make use of different sounds, and with the same effect. Thus *aurum* denotes that idea in Latin, and *or* in French; and even the word *gold* itself would have as well served to express the idea of that metal which we call *silver*, had custom in the beginning established it.

9
The connection between words and ideas, a perfectly voluntary establishment.

III. But although we are thus entirely at liberty in connecting any idea with any sound, yet it is quite otherwise in unfolding the ideas themselves. For every idea having a precise appearance of its own, by which it is distinguished from every other idea; it is so manifested, that in laying it open to others, we must represent it as it really is. Any such description as shall exhibit that peculiar appearance. When we have formed to ourselves the idea of a figure bounded by four equal sides, joined together at right angles, we are at liberty to express that idea by any sound, and call it either a *square* or a *triangle*. But whichever of these names we use, so long as the idea is the same, the description by which we would signify it to another must be so too. Let it be called *square* or *triangle*, it is still a figure having four equal sides, and all its angles right ones. Hence we clearly see what is and what is not arbitrary in the use of words. The establishing any sound as the mark of some determinate idea in the mind, is the effect of free choice, and a voluntary combination among men: and as different nations make use of different sounds to denote the same ideas, hence proceeds all that variety of languages which we meet with in the world. But when a connection between our ideas and words is once settled, the unfolding of the ideas answering to any word, which properly constitutes a definition, is by no means an arbitrary thing: for here we are bound to exhibit that precise conception which either the use of language, or our own particular choice, hath annexed to the term we use.

IV. And thus it appears, that definitions, considered as descriptions of ideas in the mind, are steady and invariable, being bounded to the representation of these precise ideas. But then, in the application of definitions to particular names, we are altogether left to our own free choice. Because as the connecting of any idea with any sound is a perfectly arbitrary institution, the applying the description of that idea to that sound must be so too. When therefore logicians tell us that the definition of the name is arbitrary, they mean no more than this; that as different ideas may

10
The description of ideas not so, but bounded by that which it is manifested, that in laying it open to others, we must represent it as it really is. Any such description as shall exhibit that peculiar appearance by which they are distinguished among themselves.

11
Causes of the obscurity by that has hitherto perplexed the theory of definitions.

be connected with any term, according to the good pleasure of him that uses it; in like manner may different descriptions be applied to the term suitable, to the ideas so connected. But this connection being settled, and the term considered as the sign of some fixed idea in the understanding, we are no longer left to arbitrary explications, but must study such a description as corresponds with that precise idea. Now this alone, according to what has been before laid down, ought to be accounted a definition. What seems to have occasioned no small confusion in this matter, is, that many explanations of words, where no idea is unfolded, but merely the connection between some word and idea asserted, have yet been dignified with the name of definitions. Thus, when we say that *a clock is an instrument by which we measure time*; that is by some called a definition; and yet it is plain that we are beforehand supposed to have an idea of this instrument, and only taught that the word *clock* serves in common language to denote that idea.

By this rule all explications of words in our dictionaries will be definitions, nay, the names of even simple ideas may be thus defined. *White*, we may say, is the colour we observe in snow or milk; *heat* the sensation produced by approaching the fire; and so in innumerable other instances. But these, and all others of the like kind, are by no means definitions, exciting new ideas in the understanding, but merely contrivances to remind us of known ideas, and teach their connection with the established names.

Complex ideas alone capable of definition which goes by the name of a definition.

V. But now in definitions properly so called, we first consider the term we use, as the sign of some inward conception, either annexed to it by custom, or our own free choice; and then the business of the definition is to unfold and explicate that idea. As therefore the whole art lies in giving just and true copies of our ideas; a definition is then said to be made perfect, when it serves distinctly to excite the idea described in the mind of another, even supposing him before wholly unacquainted with it. This point settled, let us next inquire what those ideas are which are capable of being thus unfolded? And in the first place it is evident, that all our simple ideas are necessarily excluded. We have seen already that experience alone is to be consulted here, inasmuch that if either the objects whence they are derived come not in our way, or the avenues appointed by nature for their reception, are wanting, no description is sufficient to convey them into the mind. But where the understanding is already supplied with these original and primitive conceptions, as they may be united together in an infinity of different forms; so may all their several combinations be distinctly laid open, by enumerating the simple ideas concerned in the various collections, and tracing the order and manner in which they are linked one to another. Now these combinations of simple notions constitute what we call our complex notions; whence it is evident, that complex ideas, and those alone, admit of that kind of description which goes by the name of a definition.

VI. Definitions, then, are pictures or representations of our ideas; and as these representations are then only possible when the ideas themselves are complex, it is obvious to remark, that definitions cannot have place but where we make use of terms

VOL. X. Part I.

standing for such complex ideas. But our complex ideas, being, as we have said, nothing more than different combinations of simple ideas; we then know and comprehend them perfectly, when we know the several simple ideas of which they consist, and can so put them together in our minds as may be necessary towards the framing of that peculiar connection which gives every idea its distinct and proper appearance.

VII. Two things are therefore required in every definition: first, That all the original ideas, out of which the complex one is formed, be distinctly enumerated; and, secondly, That the order and manner of combining them into one conception be clearly explained. Where a definition has these requisites, nothing is wanting to its perfection; because every one who reads it and understands the terms, seeing at once what ideas he is to join together, and also in what manner, can at pleasure form in his own mind the complex conception answering to the term defined. Let us, for instance, suppose the word *square* to stand for that idea by which we represent to ourselves a figure whose sides subtend quadrants of a circumscribed circle. The parts of this idea are the sides bounding the figure. These must be four in number, and all equal among themselves, because they are each to subtend a fourth part of the same circle. But, besides these component parts, we must also take notice of the manner of putting them together, if we would exhibit the precise idea for which the word *square* here stands. For four equal right lines, any-how joined, will not subtend quadrants of a circumscribed circle. A figure with this property must have its sides standing also at right angles. Taking in therefore this last consideration respecting the manner of combining the parts, the idea is fully described, and the definition thereby rendered complete. For a figure bounded by four equal sides, joined together at right angles, has the property required; and is moreover the only right-lined figure to which that property belongs.

VIII. It will now be obvious to every one, in what manner we ought to proceed, in order to arrive at just and adequate definitions. First, we are to take a just and exact view of the idea to be described, trace it to its original principles, and mark the several simple perceptions that enter into the composition of it. Secondly, we are to consider the particular manner in which these elementary ideas are combined, in order to the forming of that precise conception for which the term we make use of stands. When this is done, and the idea wholly unravelled, we have nothing more to do than fairly transcribe the appearance it makes to our own minds. Such a description, by distinctly exhibiting the order and number of our primitive conceptions, cannot fail to excite at the same time in the mind of every one that reads it, the complex idea resulting from them; and therefore attains the true and proper end of a definition.

CHAP. III. Of the Composition and Resolutions of our Ideas, and the Rules of Definition thence arising.

I. THE rule laid down in the foregoing chapter is general, extending to all possible cases; and is indeed that to which alone we can have recourse, where any

B b doubt

15
In com-
pounding
our ideas,
we proceed
by a suc-
cessive gra-
dation.

doubt or difficulty arises. It is not, however, necessary that we should practise it in every particular instance. Many of our ideas are extremely complicated, inso-much that to enumerate all the simple perceptions out of which they are formed, would be a very trouble-some and tedious work. For this reason logicians have established certain compendious rules of defining, of which it may not be amiss here to give some ac-count. But in order to the better understanding of what follows, it will be necessary to observe, that there is a certain gradation in the composition of our ideas. The mind of man is very limited in its views, and cannot take in a great number of objects at once. We are therefore fain to proceed by steps, and make our first advances subservient to those which follow. Thus, in forming our complex notions, we begin at first with but a few simple ideas, such as we can manage with ease, and unite them together into one conception. When we are provided with a sufficient stock of these, and have by habit and use rendered them familiar to our minds, they become the com-ponent parts of other ideas still more complicated, and form what we may call a second order of compound notions. This process, as is evident, may be continued to any degree of composition we please, mount-ing from one stage to another, and enlarging the number of combinations.

16
Hence ideas
of this class
best com-
prehended,
when we
advance
gradually
through all
the several
orders.

II. But now in a series of this kind, whoever would acquaint himself perfectly with the last and highest order of ideas, finds it much the most expedient method to proceed gradually through all the inter-mediate steps. For, were he to take any very compound idea to pieces, and, without regard to the several classes of simple perceptions that have already been formed into distinct combinations, break it at once into its original principles, the number would be so great as perfectly to confound the imagination, and overcome the utmost reach and capacity of the mind. When we see a prodigious multitude of men jumbled together in crowds, without order or any regular position, we find it impossible to arrive at an exact knowledge of their number. But if they are formed into separate bat-talions, and so stationed as to fall within the leisure survey of the eye; by viewing them successively and in order, we come to an easy and certain deter-mination. It is the same in our complex ideas. When the original perceptions, out of which they are framed, are very numerous, it is not enough that we take a view of them in loose and scattered bodies; we must form them into distinct classes, and unite these classes in a just and orderly manner, before we can arrive at a true knowledge of the compound notions resulting from them.

17
Our defini-
tions should
keep pace
with our
ideas, and
observe a
like grada-
tion.

III. This gradual progress of the mind to its com-pound notions, through a variety of intermediate steps, plainly points out the manner of conducting the definitions by which these notions are conveyed into the minds of others. For as the series begins with simple and easy combinations, and advances through a suc-cession of different orders, rising one above another in the degree of composition, it is evident, that, in a train of definitions expressing these ideas, a like gradation is to be observed. Thus the complex ideas of the lowest order can no otherwise be described than by enumerating the simple ideas out of which they are made, and explaining the manner of their union. But

then in the second, or any other succeeding order, as they are formed out of those gradual combinations, and constitute the inferior classes, it is not necessary, in describing them, to mention one by one all the sim-ple ideas of which they consist. They may be more distinctly and briefly unfolded, by enumerating the compound ideas of a lower order, from whose union they result, and which are all supposed to be already known in consequence of previous definitions. Here then it is that the logical method of defining takes place; which, that it may be the better understood, we shall explain somewhat more particularly the fe-veral steps and gradations of the mind in compounding its ideas, and thence deduce that peculiar form of a definition which logicians have thought fit to estab-lish.

IV. All the ideas we receive from the several ob-jects of nature that surround us, represent distinct in-dividuals. These individuals, when compared toge-ther, are found in certain particulars to resemble each other. Hence, by collecting the resembling particulars into one conception, we form the notion of a *species*. And here let it be observed, that this last idea is less complicated than that by which we represent any of the particular objects contained under it. For the idea of the species excludes the peculiarities of the several individuals, and retains only such properties as are common to them all. Again, by comparing several species together, and observing their resemblance, we form the idea of a *genus*; where, in the same manner as before, the composition is lessened, because we leave out what is peculiar to the several species com-pared, and retain only the particulars wherein they agree. It is easy to conceive the mind proceeding thus from one step to another, and advancing through its several classes of general notions, until at last it comes to the highest genus of all, denoted by the word *being*, where the bare idea of existence is only con-cerned.

V. In this procedure we see the mind unravelling a complex idea, and tracing it in the ascending scale, from greater or less degrees of composition, until it terminates in one simple perception. If now we take the series the contrary way, and, beginning with the last or highest genus, carry our view downwards, through all the inferior genera and species, quite to the individuals, we shall thereby arrive at a distinct apprehension of the conduct of the understanding in compounding its ideas. For, in the several classes of our perceptions, the highest in the scale is for the most part made up of but a few simple ideas, such as the mind can take in and survey with ease. This first general notion, when branched out into the different subdivisions contained under it, has in every one of them something peculiar, by which they are distin-guished among themselves; inso-much that, in de-scending from the genus to the species, we always superadd some new idea, and thereby increase the degree of composition. Thus the idea denoted by the word *figure* is of a very general nature, and com-posed of but few simple perceptions, as implying no more than space every where bounded. But if we descend farther, and consider the boundaries of this space, as that they may be either lines or surface, we fall into the several species of figure. For where the space is bounded by one or more surfaces, we give it the

18

name of a *solid figure*; but where the boundaries are lines, it is called a *plain figure* (A).

20
The idea of
the species
found by
superad-
ding the
specific dif-
ference to
the genus.

VI. In this view of things it is evident, that the species is formed by superadding a new idea to the genus. Here, for instance, the genus is circumscribed space. If now to this we superadd the idea of a circumscription by lines, we frame the notion of that species of figures which are called *plain*; but if we conceive the circumscription to be by surfaces, we have the species of solid figures. This superadded idea is called the *specific difference*, not only as it serves

to divide the species from the genus, but because, being different in all the several subdivisions, we thereby also distinguish the species one from another. And as it is likewise that conception, which, by being joined to the general idea, completes the notion of the species; hence it is plain, that the genus and specific difference are to be considered as the proper and constituent parts of the species. If we trace the progress of the mind still farther, and observe it advancing through the inferior species, we shall find its manner of proceeding to be always the same. For every lower

B b 2
species

(A) This account of the composition and resolution of our ideas is agreeable to the common doctrine of logicians on the subject. Into the truth of the doctrine itself we shall inquire afterwards under the article *METAPHYSICS*; but to prevent mistakes, it may be proper to observe here, that though every writer of logic has treated largely of *general* and *specific ideas*, there is in reality nothing *general* in the matter but the *terms of language*. When we utter, for instance, the word *triangle*, that *general term* does not, as has been often said, suggest to the mind the *general idea* of a triangle, which is neither *oblique nor rectangle*, neither *equilateral nor scalenon*, &c. for such a triangle, as it cannot exist in nature, cannot be conceived in idea. In like manner, the *general term* *Virtue* does not excite a general idea of *virtue*, which is neither *prudence*, nor *temperance*, nor *fortitude*, nor *justice*, nor *charity*, &c. for that which is *distinct* from all these is not *virtue*. What then is the import of such *general terms*? The answer is obvious: They denote *classes of objects*; and are never used without some word of limitation, but when something that has no dependence upon the *particular qualities*, which distinguish the individuals from each other, is affirmed or denied of the whole class. Thus we may affirm, that the *three angles of a plain triangle are equal to two right angles*; and this proposition is demonstrably true, not of a triangle, which is neither *oblique nor rectangle*, neither *equilateral nor scalenon*, for such a triangle never was conceived; but of *all these triangles equally*, as the truth of the proposition and the progress of the demonstration has no dependence upon the *peculiarities which distinguish* these triangles from one another. Again, when we say that a man of *virtue will be rewarded by God*, we do not mean by the word *virtue* a general idea making part of each of the complex and more particular ideas of *prudence*, *fortitude*, *justice*, &c. and at the same time different from them all; but we affirm, that the man who practices any or all of these virtues, according as he has opportunity, will be rewarded by God.

The history of our ideas is shortly this:—That act of the mind, if it may be called an *act*, which makes known an *external object*, is termed *PERCEPTION*. That act of the mind which makes known an *internal object*, is termed *CONSCIOUSNESS*. Objects once perceived may be recalled to the mind by the power of memory; and when they are so recalled, we have a perception of them in all respects similar to the original perception, only less distinct; we fancy ourselves in the same place, and the object perceived attended by the same circumstances. This indistinct secondary perception of an object is termed an *IDEA*; and therefore the precise and accurate definition of an *idea*, in contradistinction to an *original perception*, is “that perception of a real object which is raised in the mind by the power of memory.” Now all our *original perceptions* being of *particular objects*, it is obvious that our *ideas*, which are only those perceptions recalled, must be of *particular objects likewise*, and that no man can have an *idea* of a thing of which the *real existence* is contradictory and impossible. But the *general and specific ideas* of logicians, are ideas of *nothing which exists*, or *which can possibly exist*. They are acquired, we are told, by *abstraction*, in the following manner. Among a number of individuals we perceive certain qualities the same in all, whilst in each individual there are other qualities which have nothing similar to them in any other individual: now the mind, it is said, has a power of abstracting the *particular qualities* of each individual from those which are common to the whole, and of these last forming a *general idea* of the whole class. Thus all men have nearly the same form; and they have each some stature and some colour, though there are not perhaps two individuals who have *precisely the same stature and the same colour*. Now, say the advocates for general ideas, if we *abstract* what is peculiar to each individual, and retain what is common to the whole race, we have the *general idea* signified by the word *man*. That is, if we conceive a being in human shape, which is of stature and colour, but neither tall nor short, neither white nor black, nor red nor brown, nor any other colour which we ever saw, we have the *general idea* of *humanity*, and understand the meaning of the word *man*! Surely no person who is not the slave of prejudice will pretend that he can frame such an idea as this—the idea of an object which cannot possibly exist in nature.

By this we do not mean to affirm, that we cannot frame ideas of such objects as have no real existence; for it is as easy to imagine a man with ten heads as with one, because there is nothing contradictory between ten heads and one body. But figures, which is said to be space bounded neither by lines nor superficies; colour, which is neither red nor white, nor blue nor black, &c.; and animal, which is neither man, beast, bird, nor insect; are impossible in nature, and inconceivable in idea. There is, however, no harm in still retaining the phrase *general idea*, provided he who uses it takes care to let it be known, that by these words he means not any abstract and contradictory idea, but merely a class of real objects. The phrase may at times prevent much circumlocution; for which reason we have retained the use of it in the text.

species is formed by superadding some new idea to the species next above it; inasmuch that in this descending scale of our perceptions, the understanding passes through different orders of complex notions, which become more and more complicated at every step it takes. Let us resume here, for instance, the species of plain figures. They imply no more than space bounded by lines. But if we take in an additional consideration of the nature of these lines, as whether they are *right* or *curves*, we fall into the subdivisions of plain figure, distinguished by the names of *rectilinear*, *curvilinear*, and *mixtilinear*.

21 And in all the inferior species, by superadding the specific difference to the nearest genus.

VII. And here we are to observe, that though plain figures, when considered as one of those branches that come under the notion of figure in general, take the name of a species; yet compared with the classes of curvilinear, rectilinear, and mixtilinear, into which they themselves may be divided, they really become a genus, of which the before mentioned subdivisions constitute the several species. These species, in the same manner as in the case of plain and solid figures, consist of the genus and specific difference as their constituent parts. For in the curvilinear kind, the curvity of the lines bounding the figure makes what is called the *specific difference*; to which if we join the genus, which here is a plain figure or space circumscribed by lines, we have all that is necessary towards completing the notion of this species. We are only to take notice, that this last subdivision, having two genera above it, *viz.* plain figures, and figure in general; the genus joined with the specific difference, in order to constitute the species of curvilinears, is that which lies nearest to the said species. It is the notion of plain figure, and not of figure in general, that, joined with the idea of curvity, makes up the complex conception of curve-lined figures. For in this descending scale of our ideas, figure in general, plain figures, curve-lined figures, the two first are considered as genera in respect of the third; and the second in order, or that which stands next to the third, is called the *nearest genus*. But now as it is this second idea, which, joined with the notion of curvity, forms the species of curve-lined figures; it is plain, that the third or last idea in the series is made up of the nearest genus and specific difference. This rule holds invariably, however far the series is continued; because, in a train of ideas thus succeeding one another, all that precede the last are considered as so many genera in respect of that last; and the last itself is always formed by superadding the specific difference to the genus next it.

22 The idea of any individual composed of the lowest species and numeric difference.

VIII. Here then we have a universal description, applicable to all our ideas of whatever kind, from the highest genus to the lowest species. For, taking them in order downwards from the said general idea, they every where consist of the *genus proximum*, and *differentia specifica*, as logicians love to express themselves. But when we come to the lowest species of all, comprehending under it only individuals, the superadded idea, by which these individuals are distinguished one from another, no longer takes the name of the specific difference. For here it serves not to denote distinct species, but merely a variety of individuals, each of which, having a particular existence of its own, is therefore numerically different from every

other of the same kind. And hence it is, that in this last case, logicians choose to call the superadded idea by the name of the *numerical difference*; inasmuch that, as the idea of a species is made up of the nearest genus and specific difference, so the idea of an individual consists of the lowest species and numeric difference. Thus the circle is a species of curve-lined figures, and what we call the *lowest species*, as comprehending under it only individuals. Circles in particular are distinguished from one another by the length and position of their diameters. The length therefore and position of the diameter of a circle form what logicians call the *numerical difference*; because, these being given, the circle itself may be described, and an individual thereby constituted.

IX. Thus the mind, in compounding its ideas, begins, we see, with the most general notions, which, consisting of but a few simple notions, are easily combined and brought together into one conception. Thence it proceeds to the species comprehended under this general idea, and these are formed by joining together the genus and specific difference. And as it often happens, that these species may be still farther subdivided, and run on in a long series of continued gradations, producing various orders of compound perceptions; so all these several orders are regularly and successively formed by annexing in every step the specific difference to the nearest genus. When by this method of procedure we are come to the lowest order of all, by joining the species and numeric difference, we frame the ideas of individuals. And here the series necessarily terminates, because it is impossible any farther to bound or limit our conceptions. This view of the composition of our ideas, representing their constituent parts in every step of the progression, naturally points out the true and genuine form of a definition. For as definitions are no more than descriptions of the ideas for which the terms defined stand; and as ideas are then described, when we enumerate distinctly and in order the parts of which they consist; it is plain, that by making our definitions follow one another according to the natural train of our conceptions, they will be subject to the same rules, and keep pace with the ideas they describe.

X. As therefore the first order of our compound notions, or the ideas that constitute the highest genera in the different scales of perception, are formed by uniting together a certain number of simple notions; so the terms expressing these genera are defined by enumerating the simple notions so combined. And as the species comprehended under any genus, or the complex ideas of the second order, arise from superadding the specific difference to the said general idea; so the definition of the names of the species is abolished, in a detail of the ideas of the specific difference, connected with the term of the genus. For the genus having been before defined, the term by which it is expressed stands for a known idea, and may therefore be introduced into all subsequent definitions, in the same manner as the names of simple perceptions. It will now be sufficiently obvious, that the definitions of all the succeeding orders of compound notions will every where consist of the term of the nearest genus, joined with an enumeration of the ideas that constitute the specific

23 Definitions to follow one another in train, and pass thro' the five gradations as out ideas.

24 The form of a definition in all the various orders of conception.

specific difference; and that the definition of individuals unites the names of the lowest species with the terms by which we express the ideas of the numeric difference.

XI. Here then we have the true and proper form

of a definition, in all the various orders of conception. This is that method of defining which is commonly called *logical*, and which we see is perfect in its kind, inasmuch as it presents a full and adequate description of the idea for which the term defined stands.

PART II. OF JUDGMENT.

CHAP. I. Of the Grounds of Human Judgment.

25
Intuition respects the relations between our ideas when they are immediately perceptible.

THE mind being furnished with ideas, its next step in the way to knowledge is, the comparing these ideas together, in order to judge of their agreement or disagreement. In this joint view of our ideas, if the relation is such as to be immediately discoverable by the bare inspection of the mind, the judgments then obtained are called *intuitions*, from a word that denotes to *look at*; for in this case, a mere attention to the ideas compared suffices to let us see how far they are connected or disjointed. Thus, *that the Whole is greater than any of its Parts*, is an intuitive judgment; nothing more being required to convince us of its truth, than an attention to the ideas of *whole* and *part*. And this too is the reason why we call the act of the mind forming these judgments *intuition*; as it is indeed no more than an immediate perception of the agreement or disagreement of any two ideas.

26
Experience and testimony only the ground of judging as to facts.

II. But here it is to be observed, that our knowledge of this kind respects only our ideas, and the relations between them; and therefore can serve only as a foundation to such reasonings as are employed in investigating those relations. Now it so happens, that many of our judgments are conversant about facts, and the real existence of things, which cannot be traced by the bare contemplation of our ideas. It does not follow, because I have the idea of a circle in my mind, that therefore a figure answering to that idea has a real existence in nature. I can form to myself the notion of a centaur or golden mountain, but never imagine on that account that either of them exists. What then are the grounds of our judgment in relation to facts? *experience* and *testimony*. By experience we are informed of the existence of the several objects which surround us, and operate upon our senses. Testimony is of a wider extent, and reaches not only to objects beyond the present sphere of our observation, but also to facts and transactions, which being now past, and having no longer any existence, could not without this conveyance have fallen under our cognizance.

27
Three foundations of human judgment, viz. 1. Intuition, the ground of scientific knowledge.

III. Here we have three foundations of human judgment, from which the whole system of our knowledge may with ease and advantage be derived. First, intuition, which respects our ideas themselves, and their relations; and is the foundation of that species of reasoning which we call *demonstration*. For whatever is deduced from our intuitive perceptions, by a clear and connected series of proofs, is said to be demonstrated, and produces absolute certainty in the mind. Hence the knowledge obtained in this manner is what we properly term *science*; because in every step of the procedure it carries its own evidence along with it, and leaves no room for doubt or hesitation.

And what is highly worthy of notice; as the truths of this class express the relation between our ideas, and the same relations must ever and invariably subsist between the same ideas, our deductions in the way of science constitute what we call *eternal, necessary, and immutable truths*. If it be true that the whole is equal to all its parts, it must be so unchangeably; because the relation of equality being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature are all the truths of natural religion, morality, and mathematics, and in general whatever may be gathered from the bare view and consideration of our ideas.

IV. The second ground of human judgment is *experience*; from which we infer the existence of those subjects that surround us, and fall under the immediate notice of our senses. When we see the sun, or cast our eyes towards a building, we not only have perceptions of these objects within ourselves, but ascribe to them a real existence out of the mind. It is also by the information of the senses that we judge of the qualities of bodies; as when we say that *snow is white, fire hot, or steel hard*. For as we are wholly unacquainted with the internal structure and constitution of the bodies that produce these sensations in us, nay, and are unable to trace any connection between that structure and the sensations themselves, it is evident, that we build our judgments altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions they excite in us. Not that we ever suppose the qualities of bodies to be things of the same nature with our perceptions; for there is nothing in fire similar to our sensation of heat, or in a sword similar to pain: but that when different bodies excite in our minds similar perceptions, we necessarily ascribe to these bodies not only an existence independent of us, but likewise similar qualities, of which it is the nature to produce similar perceptions in the human mind. But this is not the only advantage derived from experience; for to that too we are indebted for all our knowledge regarding the coexistence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic; this we know by experience, and indeed by that alone. For, being altogether strangers to the true nature both of elasticity and hardness, we cannot by the bare contemplation of our ideas determine how far the one necessarily implies the other, or whether there may not be a repugnance between them. But when we observe them to exist both in the same object, we are then assured from experience that they are not incompatible; and when we also find, that a stone is hard and not elastic, and that air though elastic is not hard, we also conclude upon the same foundation, that the ideas are not necessarily conjoined,

but may exist separately in different objects. In like manner with regard to the operations of bodies one upon another, it is evident, that our knowledge this way is all derived from observation. *Aquaregia* dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of *aquaregia* are of a texture apt to insinuate between the corpuscles of gold, and thereby loosen and shake them asunder. If this is a true account of the matter, it will notwithstanding be allowed, that our conjecture in regard to the conformation of these bodies is deduced from the experiment, and not the experiment from the conjecture. It was not from any previous knowledge of the intimate structure of *aquaregia* and gold, and the aptness of their parts to act or to be acted upon, that we came by the conclusion above mentioned. The internal constitution of bodies is in a manner wholly unknown to us; and could we even surmount this difficulty, yet as the separation of the parts of gold implies something like an active force in the *menstruum*, and we are unable to conceive how it comes to be possessed of this activity, the effect must be owned to be altogether beyond our comprehension. But when repeated trials had once confirmed it, inasmuch that it was admitted as an established truth in natural knowledge, it was then easy for men to spin out theories of their own invention, and contrive such a structure of parts, both for *gold* and *aquaregia*, as would best serve to explain the phenomenon upon the principles of that system of philosophy they had adopted.

V. From what has been said it is evident, that as intuition is the foundation of what we call *scientific* knowledge, so is experience of *natural*. For this last being wholly taken up with objects of sense, or those bodies that constitute the natural world; and their properties, as far as we can discover them, being to be traced only by a long and painful series of observations; it is apparent, that, in order to improve this branch of knowledge, we must betake ourselves to the method of trial and experiment.

VI. But though experience is what we may term the immediate foundation of natural knowledge, yet with respect to particular persons its influence is very narrow and confined. The bodies that surround us are numerous, many of them lie at a great distance, and some quite beyond our reach. Life is so short, and so crowded with cares, that but little time is left for any single man to employ himself in unfolding the mysteries of nature. Hence it is necessary to admit many things upon the testimony of others, which by this means becomes the foundation of a great part of our knowledge of body. No man doubts of the power of *aquaregia* to dissolve gold, though perhaps he never himself made the experiment. In these therefore and such like cases we judge of the facts and operations of nature upon the mere ground of testimony. However, as we can always have recourse to experience where any doubt or scruple arises, this is justly considered as the true foundation of natural philosophy; being indeed the ultimate support upon which our assent rests, and whereto we appeal when the highest degree of evidence is required.

VII. But there are many facts that will not allow

of an appeal to the senses; and in this case testimony is the true and only foundation of our judgments. All human actions of whatever kind, when considered as already past, are of the nature here described; because having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of such as had sufficient opportunities of arriving at the truth. *Testimony* therefore is justly accounted a third ground of human judgment; and as from the other two we have deduced *scientific* and *natural* knowledge, so we may from this derive *historical*; by which we mean, not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

CHAP. II. Of Affirmative and Negative Propositions.

I. WHILE the comparing of our ideas is considered merely as an act of the mind, assembling them together, and joining or disjoining them according to the result of its perceptions, we call it *judgment*; but when our judgments are put into words, they then bear the name of *propositions*. A proposition therefore is a sentence expressing some judgment of the mind, whereby two or more ideas are affirmed to agree or disagree. Now, as our judgments include at least two ideas, one of which is affirmed or denied of the other, so must a proposition have terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the *subject* of the proposition. The idea affirmed or denied, as also the term answering it, is called the *predicate*. Thus in the proposition, *God is omnipotent*: *God* is the subject, it being of him that we affirm omnipotence; and *omnipotent* is the predicate, because we affirm the idea expressed by that word to belong to God.

II. But as, in propositions, ideas are either joined or disjoined; it is not enough to have terms expressing those ideas, unless we have also some words to denote their agreement or disagreement. That word in a proposition, which connects two ideas together, is called the *copula*; and if a negative particle be annexed, we thereby understand that the ideas are disjoined. The *substantive verb* is commonly made use of for the copula: as in the above-mentioned proposition, *God is omnipotent*; where *is* represents the copula, and signifies the agreement of the ideas of *God* and *omnipotence*. But if we mean to separate two ideas; then, besides the substantive verb, we must also use some particle of negation, to express this repugnance. The proposition, *man is not perfect*, may serve as an example of this kind; where the notion of *perfection* being removed from the idea of *man*, the negative particle *not* is inserted after the copula, to signify the disagreement between the subject and predicate.

III. Every proposition necessarily consists of these three parts: but then it is not alike needful that they be all severally expressed in words; because the copula is often included in the term of the predicate, as when a single word, *he sits*; which imports the same as *he is sitting*. In the Latin language, a single word has often the force of a whole sentence. Thus *ambulat* is the same as *ille est ambulans*; *amo*, as *ego sum amans*; and so in

innumerable other instances: by which it appears, that we are not so much to regard the number of words in a sentence, as the ideas they represent, and the manner in which they are put together. For wherever two ideas are joined or disjoined in an expression, tho' of but a single word; it is evident that we have a subject, predicate, and copula, and of consequence a complete proposition.

33
Affirmative
and negative
proposi-
tions.

IV. When the mind joins two ideas, we call it an *affirmative* judgment; when it separates them, a *negative*: and as any two ideas compared together must necessarily either agree or not agree, it is evident that all our judgments fall under these two divisions. Hence likewise the propositions expressing these judgments are all either affirmative or negative. An affirmative proposition connects the predicate with the subject, as *a stone is heavy*; a negative proposition separates them, as *God is not the author of evil*. Affirmation therefore is the same as joining two ideas together, and this is done by means of the copula. Negation on the contrary marks a repugnance between the ideas compared; in which case a negative particle must be called in, to show that the connection included in the copula does not take place.

34
When the
negative
particle
serves to
disjoin
ideas.

V. Hence we see the reason of the rule commonly laid down by logicians, That in all negative propositions the negation ought to affect the copula. For as the copula, when placed by itself, between the subject and the predicate, manifestly binds them together; it is evident, that in order to render a proposition negative, the particles of negation must enter it in such a manner as to destroy this union. In a word, then only are two ideas disjoined in a proposition, when the negative particle may be so referred to the copula, as to break the affirmation included in it, and undo that connection it would otherwise establish. When we say, for instance, *No man is perfect*; take away the negation, and the copula of itself plainly unites the ideas in the proposition. But as this is the very reverse of what is intended, a negative mark is added, to show that this union does not here take place. The negation, therefore, by destroying the effect of the copula, changes the very nature of the proposition, inasmuch that, instead of binding two ideas together, it denotes their separation. On the contrary, in this sentence, *The man who departs not from an upright behaviour is beloved of God*, the predicate *beloved of God* is evidently affirmed of the subject *an upright man*; so that, notwithstanding the negative particle, the proposition is still affirmative. The reason is plain: the negation here affects not the copula; but, making properly a part of the subject, serves, with other terms in the sentence, to form one complex idea, of which the predicate *beloved of God* is directly affirmed.

CHAP. III. Of Universal and Particular Propositions.

I. THE next considerable division of propositions is

into *universal* and *particular*. Our ideas, according to what has been already observed in the First Part, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once; hence the terms expressing these ideas must be in like manner universal. If therefore we suppose any general term to become the subject of a proposition, it is evident, that whatever is affirmed of the abstract idea belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus, when we say, *Men are mortal*; we consider mortality, not as confined to one or any number of particular men, but as what may be affirmed without restriction of the whole species. By this means the proposition becomes as general as the idea which makes the subject of it; and indeed derives its universality entirely from that idea, being more or less so according as this may be extended to more or fewer individuals. But it is further to be observed of these general terms, that they sometimes enter a proposition in their full latitude, as in the example given above; and sometimes appear with a mark of limitation. In this last case we are given to understand, that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition, *Some men are wise*: For here wisdom is not affirmed of every particular man, but restrained to a few of the human species (B).

II. Now from this different appearance of the general idea that constitutes the subject of any judgment, arises the division of propositions into *universal* and *particular*. An universal proposition is that wherein the subject is some general term taken in its full latitude; inasmuch that the predicate agrees to all the individuals comprehended under it, if it denotes a proper species; and to all the several species, and their individuals, if it marks an idea of a higher order. The words *all*, *every*, *no*, *none*, &c. are the proper signs of this universality; and as they seldom fail to accompany general truths, so they are the most obvious criterion whereby to distinguish them. *All animals have a power of beginning motion*. This is an universal proposition; as we know from the word *all* prefixed to the subject *animals*, which denotes that it must be taken in its full extent. Hence the power of beginning motion may be affirmed of all the several species of animals.

III. A particular proposition has in like manner some general term for its subject; but with a mark of limitation added, to denote, that the predicate agrees only to some of the individuals comprehended under a species, or to one or more of the species belonging to any genus, and not to the whole universal idea. Thus, *Some stones are heavier than iron*: *Some men have an uncommon share of prudence*. In the last of these propositions, the subject *some men* implies only a certain number.

36

is so, with-
out a mark
of restric-
tion.

37
Proposi-
tions parti-
cular where
some uni-
versal sub-
ject appears
with a mark
of limita-
tion.

(B) See the preceding note, where it is demonstrated that the *terms* alone, and not the *ideas*, are in reality general. The term *man* is equally applicable to every individual of the human race; and therefore, what is affirmed or denied of *men* in general, is affirmed or denied of all the individuals, without regard to their discriminating qualities. *Some* is a definitive word (see GRAMMAR), which, prefixed to the word *man*, limits the signification of that general term; and therefore what is affirmed of *some men*, is affirmed only of *part* of the race, but that part itself is not ascertained.

ber of individuals, comprehended under a single species. In the former, where the subject is a genus that extends to a great variety of distinct classes, *some stones* may not only imply any number of particular stones, but also several whole species of stones, inasmuch as there may be not a few with the property there described. Hence we see, that a proposition does not cease to be particular by the predicate's agreeing to a whole species, unless that species, singly and distinctly considered, makes also the subject of which we affirm or deny.

38
Singular propositions contained under the head of particulars

IV. There is still one species of propositions that remains to be described, and which the more deserves our notice, as it is not yet agreed among logicians to which of the two classes mentioned above they ought to be referred; namely, *singular propositions*, or those where the subject is an individual. Of this nature are the following: *Sir Isaac Newton was the inventor of fluxions; This book contains many useful truths.* What occasions some difficulty as to the proper rank of these propositions is, that, the subject being taken according to the whole of its extension, they sometimes have the same effect in reasoning as universals. But if it be considered that they are in truth the most limited kind of particular propositions, and that no proposition can with any propriety be called universal but where the subject is some universal idea; we shall not be long in determining to which class they ought to be referred. When we say, *Some books contain useful truths*; the proposition is particular, because the general term appears with a mark of restriction. If therefore we say, *This book contains useful truths*; it is evident that the proposition must be still more particular, as the limitation implied in the word *this* is of a more confined nature than in the former case.

39
The fourfold division of propositions.

V. We see, therefore, that all propositions are either *affirmative or negative*; nor is it less evident, that in both cases they may be *universal or particular*. Hence arises that celebrated fourfold division of them into *universal affirmative and universal negative, particular affirmative and particular negative*, which comprehends indeed all their varieties. The use of this method of distinguishing them will appear more fully afterwards, when we come to treat of reasoning and syllogism.

CHAP. IV. Of Absolute and Conditional Propositions.

40
Distinction of qualities into essential and accidental.

I. THE objects about which we are chiefly conversant in this world, are all of a nature liable to change. What may be affirmed of them at one time, cannot often at another; and it makes no small part of our knowledge to distinguish rightly these variations, and trace the reasons upon which they depend. For it is observable, that amidst all the vicissitude of nature, some things remain constant and invariable; nor even are the changes, to which we see others liable, effected but in consequence of uniform and steady laws, which, when known, are sufficient to direct us in our judgments about them. Hence philosophers, in distinguishing the objects of our perception into various classes, have been very careful to note, that some properties belong essentially to the general idea, so as not to be separable from it but by destroying its very nature; while others are only accidental, and may be affirmed or denied of it in different circumstances.

N^o 185.

Thus solidity, a yellow colour, and great weight, are considered as essential qualities of gold; but whether it shall exist as an uniform conjoined mass, is not unlike necessary. We see that by a proper menstruum it may be reduced to a fine powder, and that an intense heat will bring it into a state of fusion.

II. From this diversity in the several qualities of things arises a considerable difference as to the manner of our judging about them. For all such properties as are inseparable from objects when considered as belonging to any genus or species, are affirmed absolutely and without reserve of that general idea. Thus we say, *Gold is very weighty; A stone is hard; Animals have a power of self-motion.* But in the case of mutual or accidental qualities, as they depend upon some other consideration distinct from the general idea; that also must be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very fusible of a rolling motion; the proposition, while it remains in this general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion flows from the figure of the stone; which, as it may vary infinitely, our judgment then only becomes applicable and determinate, when the particular figure, of which volubility is a consequence, is also taken into the account. Let us then bring in this other consideration, and the proposition will run as follows: *Stones of a spherical form are easily put into a rolling motion.* Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.

III. This consideration of propositions respecting the manner in which the predicate is affirmed of the subject gives rise to the division of them into *absolute and conditional*. *Absolute* propositions are those where, in we affirm some property inseparable from the idea of the subject, and which therefore belongs to it in all possible cases: as, *God is infinitely wise; Virtue tends to the ultimate happiness of man.* But where the predicate is not necessarily connected with the idea of the subject, unless upon some consideration distinct from that idea, there the proposition is called *conditional*. The reason of the name is taken from the supposition annexed, which is of the nature of a condition, and may be expressed as such, thus: *If a stone is exposed to the rays of the sun, it will contract some degree of heat; If a river runs in a very declining channel, its rapidity will constantly increase.*

IV. There is not any thing of greater importance in philosophy than a due attention to this division of propositions. If we are careful never to affirm things of absolutely but where the ideas are inseparably conjoined; and if in our other judgments we distinctly mark the conditions which determine the predicate to belong to the subject; we shall be the less liable to mistake in applying general truths to the particular concerns of human life. It is owing to the exact observance of this rule that mathematicians have been so happy in their discoveries, and that what they demonstrate of magnitude in general may be applied with ease in all obvious occurrences.

V. The truth of it is, particular propositions are then known to be true, when we can trace their connection

⁴⁶
And reduc-
es them
from par-
ticulars to
generals.

nection with universals; and it is accordingly the great business of science to find out general truths that may be applied with safety in all obvious instances. Now the great advantage arising from determining with care the conditions upon which one idea may be affirmed or denied of another is this: that thereby particular propositions really become universal, may be introduced with certainty into our reasonings, and serve as standards to conduct and regulate our judgments. To illustrate this by a familiar instance: if we say, *Some water acts very forcibly*; the proposition is particular: and as the conditions on which this forcible action depends are not mentioned, it is as yet uncertain in what cases it may be applied. Let us then supply these conditions, and the proposition will run thus: *Water conveyed in sufficient quantity along a steep descent acts very forcibly*. Here we have an universal judgment, inasmuch as the predicate forcible action may be ascribed to all water under the circumstances mentioned. Nor is it less evident that the proposition in this new form is of easy application; and in fact we find that men do apply it in instances where the forcible action of water is required; as in corn-mills and many other works of art.

CHAP. V. Of Simple and Compound Propositions.

⁴⁵
Division of
proposi-
tions into
simple and
compound.

I. HITHERTO we have treated of propositions, where only two ideas are compared together. These are in the general called *simple*; because, having but one subject and one predicate, they are the effect of a simple judgment that admits of no subdivision. But if it so happens that several ideas offer themselves to our thoughts at once, whereby we are led to affirm the same thing of different objects, or different things of the same object; the propositions expressing these judgments are called *compound*: because they may be resolved into as many others as there are subjects or predicates in the whole complex determination on the mind. Thus, *God is infinitely wise and infinitely powerful*. Here there are two predicates, *infinite wisdom and infinite power*, both affirmed of the same subject; and accordingly the proposition may be resolved into two others, affirming these predicates severally. In like manner in the proposition, *Neither kings nor people are exempt from death*; the predicate is denied of both subjects, and may therefore be separated from them in distinct propositions. Nor is it less evident, that if a complex judgment consists of several subjects and predicates, it may be resolved into as many simple propositions as are the number of different ideas compared together. *Riches and honours are apt to elate the mind, and increase the number of our desires*. In this judgment there are two subjects and two predicates, and it is at the same time apparent that it may be resolved into four distinct propositions. *Riches are apt to elate the mind. Riches are apt to increase the number of our desires. And so of honours*.

⁴⁶
The proper
notion of a
compound
proposition
ascertained

II. Logicians have divided these compound propositions into a great many different classes; but, in our opinion, not with a due regard to their proper definition. Thus *conditionals, causals, relatives, &c.* are mentioned as so many distinct species of this kind, though in fact they are no more than simple propositions. To give an instance of a conditional; *If a stone is exposed to the rays of the sun, it will contract*

some degree of heat. Here we have but one subject and one predicate; for the complex expression, *A stone exposed to the rays of the sun*, constitutes the proper subject of this proposition, and is no more than one determined idea. The same thing happens in causals. *Rehobam was unhappy because he followed evil counsel*. There is here an appearance of two propositions arising from the complexity of the expression; but when we come to consider the matter more nearly, it is evident that we have but a single subject and predicate. *The pursuit of evil counsel brought misery upon Rehobam*. It is not enough, therefore, to render a proposition compound, that the subject and predicate are complex notions, requiring sometimes a whole sentence to express them: for in this case the comparison is still confined to two ideas, and constitutes what we call a simple judgment. But where there are several subjects or predicates, or both, as the affirmation or negation may be alike extended to them all, the proposition expressing such a judgment is truly a collection of as many simple ones as there are different ideas compared. Confining ourselves therefore to this more strict and just notion of compound propositions, they are all reducible to two kinds, viz. *copulatives and disjunctives*.

III. A *copulative* proposition is, where the subjects ⁴⁷Compound and predicates are so linked together, that they may proposition be all severally affirmed or denied one of another. Of ⁴⁸disjunctive, either copulative; this nature are the examples of compound propositions given above. *Riches and honours are apt to elate the mind, and increase the number of our desires. Neither kings nor people are exempt from death*. In the first of these the two predicates may be affirmed severally of each subject, whence we have four distinct propositions. The other furnishes an example of the negative kind, where the same predicate, being disjoined from both subjects, may be also denied of them in separate propositions.

IV. The other species of compound propositions are those called *disjunctives*; in which, comparing several predicates with the same subject; we affirm that one of them necessarily belongs to it, but leave the particular predicate undetermined. If any one, for example, says, *This world either exists of itself, or is the work of some all-wise and powerful cause*, it is evident that one of the two predicates must belong to the world; but as the proposition determines not which, it is therefore of the kind we call *disjunctive*. Such too are the following: *The sun either moves round the earth, or is the centre about which the earth revolves. Friendship finds men equal, or makes them so*. It is the nature of all propositions of this class, supposing them to be exact in point of form, that upon determining the particular predicate, the rest are of course to be removed; or if all the predicates but one are removed, that one necessarily takes place. Thus, in the example given above; if we allow the world to be the work of some wise and powerful cause, we of course deny it to be self-existent; or if we deny it to be self-existent, we must necessarily admit that it was produced by some wise and powerful cause. Now this particular manner of linking the predicates together, so that the establishing one displaces all the rest; or the excluding all but one necessarily establishes that one; cannot otherwise be effected than by means of *disjunctive* C c

judice particles. And hence it is that propositions of this class take their names from these particles which make so necessary a part of them, and indeed constitute their very nature considered as a distinct species.

CHAP VI. Of the Division of Propositions into Self-evident and Demonstrable.

⁴⁹
Propositions divided into self-evident and demonstrable.

I. WHEN any proposition is offered to the view of the mind, if the terms in which it is expressed be understood; upon comparing the ideas together, the agreement or disagreement asserted is either immediately perceived, or found to lie beyond the present reach of the understanding. In the first case the proposition is said to be *self-evident*, and admits not of any proof, because a bare attention to the ideas themselves produces full conviction and certainty; nor is it possible to call in any thing more evident by way of confirmation. But where the connection or repugnance comes not so readily under the inspection of the mind, there we must have recourse to reasoning; and if by a clear series of proofs we can make out the truth proposed, inasmuch that self-evidence shall accompany every step of the procedure, we are then able to demonstrate what we assert, and the proposition itself is said to be *demonstrable*. When we affirm, for instance, that it is impossible for the same thing to be and not to be; whoever understands the terms made use of perceives at first glance the truth of what is asserted, nor can he by any efforts bring himself to believe the contrary. The proposition therefore is *self-evident*, and such that it is impossible by reasoning to make it plainer; because there is no truth more obvious or better known, from which as a consequence it may be deduced. But if we say, *This world had a beginning*; the assertion is indeed equally true, but shines not forth with the same degree of evidence. We find great difficulty in conceiving how the world could be made out of nothing: and are not brought to a free and full consent, until by reasoning we arrive at a clear view of the absurdity involved in the contrary supposition. Hence this proposition is of the kind we call *demonstrable*, inasmuch as its truth is not immediately perceived by the mind, but yet may be made appear by means of others more known and obvious, whence it follows as an unavoidable consequence.

II. From what has been said, it appears, that reasoning is employed only about demonstrable propositions, and that our intuitive and self-evident perceptions are the ultimate foundation on which it rests.

⁵⁰
Self-evident truths the first principles of reasoning.

III. Self-evident propositions furnish the first principles of reasoning; and it is certain, that if in our researches we employ only such principles as have this character of self-evidence, and apply them according to the rules to be afterwards explained, we shall be in no danger of error in advancing from one discovery to another. For this we may appeal to the writings of the mathematicians, which being conducted by the express model here mentioned, are an incontestable proof of the firmness and stability of human knowledge, when built upon so sure a foundation. For not only have the propositions of this science stood the test of ages; but are found attended with that invincible evidence, as forces the assent of all who duly con-

sider the proofs upon which they are established. Since the mathematicians are universally allowed to have hit upon the right method of arriving at unknown truths, since they have been the happiest in the choice as well as the application of their principles, it may not be amiss to explain here their method of stating self-evident propositions, and applying them to the purposes of demonstration.

IV. First then it is to be observed, that they have been very careful in ascertaining their ideas, and fixing the signification of their terms. For this purpose they begin with *definitions*, in which the meaning of their words is so distinctly explained, that they can never fail to excite in the mind of an attentive reader the very same ideas as are annexed to them by the writer. And indeed the clearness and irrefragable evidence of mathematical knowledge is owing to nothing so much as this care in laying the foundation. Where the relation between any two ideas is accurately and justly traced, it will not be difficult for another to comprehend that relation, if in setting himself to discover it he brings the very same ideas into comparison. But if, on the contrary, he affixes to his words ideas different from those that were in the mind of him who first advanced the demonstration; it is evident, that as the same ideas are not compared, the same relation cannot subsist, inasmuch that a proposition will be rejected as false, which, had the terms been rightly understood, must have appeared incontestably true. A square, for instance, is a figure bounded by four equal right lines, joined together at right angles. Here the nature of the angles makes no less a part of the idea than the equality of the sides; and many properties demonstrated of the square flow entirely from its being a rectangular figure. If therefore we suppose a man, who has formed a partial notion of a square, comprehending only the equality of its sides, without regard to the angles, reading some demonstration that implies also this latter consideration; it is plain he would reject it as not universally true, inasmuch as it could not be applied where the sides were joined together at equal angles. For this last figure, answering still to his idea of a square, would be yet found without the property assigned to it in the proposition. But if he comes afterwards to correct his notion, and render his idea complete, he will then readily own the truth and justness of the demonstration.

V. We see, therefore, that nothing contributes so much to the improvement and certainty of human knowledge, as the having determinate ideas, and keeping them steady and invariable in all our discourses and reasonings about them. And on this account it is, that mathematicians, as was before observed, always begin by defining their terms, and distinctly unfolding the notions they are intended to express. Hence such as apply themselves to these studies have exactly the same views of things; and, bringing always the very same ideas into comparison, readily discern the relations between them. It is likewise of importance, in every demonstration, to express the same idea invariably by the same word. From this practice mathematicians never deviate; and if it be necessary in their demonstrations, where the reader's comprehension is aided by a diagram, it is much more so in all reasonings about moral or intellectual truths where the ideas

cannot be represented by a diagram. The observation of this rule may sometimes be productive of ill-sounding periods; but when *truth* is the object, *found* ought to be despised.

⁵³
The establishing of principles, the consequence, in mathematical knowledge.

VI. When the mathematicians have taken this first step, and made known the ideas whose relations they intend to investigate; their next care is, to lay down some self-evident truths, which may serve as a foundation for their future reasonings. And here indeed they proceed with remarkable circumspection, admitting no principles but what flow immediately from their definitions, and necessarily force themselves upon a mind in any degree attentive to its ideas. Thus a *circle* is a figure formed by a right line moving round some fixed point in the same plane. The fixed point round which the line is supposed to move, and where one of its extremities terminates, is called the *centre* of the circle. The other extremity, which is conceived to be carried round until it returns to the point whence it first set out, describes a curve running into itself, and termed the *circumference*. All right lines drawn from the centre to the circumference are called *radii*. From these definitions compared, geometers derive this self-evident truth; *that the radii of the same circle are all equal to one another*.

⁵⁴
Propositions divided into speculative and practical.

VII. We now observe, that in all propositions we either affirm or deny some property of the idea that constitutes the subject of our judgment, or we maintain that something may be done or effected. The first sort are called *speculative* propositions, as in the example mentioned above, the *radii of the same circle are all equal to one another*. The others are called *practical*, for a reason too obvious to be mentioned; thus, *that a right line may be drawn from one point to another* is a practical proposition; inasmuch as it expresses that something may be done.

⁵⁵
Hence mathematical principles distinguished into axioms and postulates.

VIII. From this twofold consideration of propositions arises the twofold division of mathematical principles into axioms and postulates. By an *axiom* they understand any self-evident speculative truth; as, *That the whole is greater than its parts: That things equal to one and the same thing are equal to one another*. But a self-evident practical proposition is what they call a *postulate*. Such are those of Euclid; *that a finite right line may be continued directly forwards; that a circle may be described about any centre with any distance*. And here we are to observe, that as in an axiom the agreement or disagreement between the subject and predicate must come under the immediate inspection of the mind; so in a postulate, not only the possibility of the thing asserted must be evident at first view, but also the manner in which it may be effected. For where this manner is not of itself apparent, the proposition comes under the notion of the demonstrable

kind, and is treated as such by geometrical writers. Thus, *to draw a right line from one point to another*, is assumed by Euclid as a postulate, because the manner of doing it is so obvious, as to require no previous teaching. But then it is not equally evident, how we are to construct an equilateral triangle. For this reason he advances it as a demonstrable proposition, lays down rules for the exact performance, and at the same time proves, that if these rules are followed, the figure will be justly described.

IX. This leads us to take notice, that as self-evident truths are distinguished into different kinds, according as they are speculative or practical; so is it also with demonstrable propositions. A demonstrable speculative proposition is by mathematicians called a *theorem*. Such is the famous 47th proposition of the first book of the elements, known by the name of the *Pythagoric theorem*, from its supposed inventor Pythagoras, viz. "that in every right-angled triangle, the square described upon the side subtending the right-angle is equal to both the squares described upon the sides containing the right-angle." On the other hand, a demonstrable practical proposition is called a *problem*; as where Euclid teaches us to describe a square upon a given right-line.

X. It may not be amiss to add, that, besides the four kinds of propositions already mentioned, mathematicians have also a fifth, known by the name of *corollaries*. These are usually subjoined to theorems or problems, and differ from them only in this; that they flow from what is there demonstrated in so obvious a manner as to discover their dependence upon the proposition whence they are deduced, almost as soon as proposed. Thus Euclid having demonstrated, "that in every right-lined triangle all the three angles taken together are equal to two right-angles;" adds by way of corollary, "that all the three angles of any one triangle taken together are equal to all the three angles of any other triangle taken together;" which is evident at first sight; because in all cases they are equal to two right ones, and things equal to one and the same thing are equal to one another.

XI. The scholars of mathematicians are indifferently annexed to definitions, propositions, or corollaries; and answer the same purposes as annotations upon a classic author. For in them occasion is taken to explain whatever may appear intricate and obscure in a train of reasoning; to answer objections; to teach the application and uses of propositions; to lay open the original and history of the several discoveries made in the science; and, in a word, to acquaint us with all such particulars as deserve to be known, whether considered as points of curiosity or profit.

⁵⁸
Remote relations discovered by means of intermediate ideas.

XII. When, for instance, we compare two figures of a different make, in order to judge of their equality or inequality, it is plain, that by barely considering the figures themselves, we cannot arrive at an exact determination; because, by reason of their disagreeing forms, it is impossible so to put them together, as that their several parts shall mutually coincide. Here then it be-

PART III. OF REASONING.

CHAP. I. Of Reasoning in general, and the Parts of which it consists.

IT often happens in comparing ideas together, that their agreement or disagreement cannot be discerned at first view, especially if they are of such a nature as not to admit of an exact application one to another.

⁵⁹
Remote relations discovered by means of intermediate ideas.

comes necessary to look out for some third idea that will admit of such an application as the present case requires; wherein if we succeed, all difficulties vanish, and the relation we are in quest of may be traced with ease. Thus right-lined figures are all reduced to squares, by means of which we can measure their areas, and determine exactly their agreement or disagreement in point of magnitude.

60
This manner of arriving at truth termed reasoning.

II. But how can any third idea serve to discover a relation between two others? The answer is, By being compared severally with these others; for such a comparison enables us to see how far the ideas with which this third is compared are connected or disjointed between themselves. In the example mentioned above of two right-lined figures, if we compare each of them with some square whose area is known, and find the one exactly equal to it, and the other less by a square inch, we immediately conclude that the area of the first figure is a square inch greater than that of the second. This manner of determining the relation between any two ideas, by the intervention of some third with which they may be compared, is that which we call *reasoning*; and is indeed the chief instrument by which we push on our discoveries, and enlarge our knowledge. The great art lies in finding out such intermediate ideas, as, when compared with the others in the question, will furnish evident and known truths; because, as will afterwards appear, it is only by means of them that we arrive at the knowledge of what is hidden and remote.

61
The parts that constitute an act of reasoning and a syllogism.

III. Hence it appears, that every act of reasoning necessarily includes three distinct judgments; two wherein the ideas whose relation we want to discover are severally compared with the middle idea, and a third wherein they are themselves connected or disjointed, according to the result of that comparison. Now, as in the second part of logic our judgments, when put into words, were called propositions, so here in the third part the expressions of our reasonings are termed *syllogisms*. And hence it follows, that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. When a reasoning is thus put into words, and appears in form of a syllogism, the intermediate idea made use of, to discover the agreement or disagreement we search for, is called the *middle term*; and the two ideas themselves, with which this third is compared, go by the name of the *extremes*.

62
Inference, man and accountable nouns.

IV. But as these things are best illustrated by examples; let us, for instance, set ourselves to inquire *whether men are accountable for their actions*. As the relation between the ideas of *man* and *accountableness* comes not within the immediate view of the mind, our first care must be to find out some third idea that will enable us the more easily to discover and trace it. A very small measure of reflection is sufficient to inform us, that no creature can be accountable for his actions, unless we suppose him capable of distinguishing the good from the bad; that is, unless we suppose him possessed of reason. Nor is this alone sufficient. For what would it avail him to know good from bad actions, if he had no freedom of choice, nor could avoid the one and pursue the other? hence it becomes necessary to take in both considerations in the present case. It is at the same time equally apparent, that

wherever there is this ability of distinguishing good from bad actions, and of pursuing the one and avoiding the other, there also a creature is accountable. We have then got a third idea, with which *accountableness* is inseparably connected, viz. *reason and liberty*; which are here to be considered as making up one complex conception. Let us now take this middle idea, and compare it with the other term in the question, viz. *man*, and we all know by experience that it may be affirmed of him. Having thus by means of the intermediate idea formed two several judgments, viz. *that man is possessed of reason and liberty*; and *that reason and liberty imply accountableness*; a third obviously and necessarily follows, viz. *that man is accountable for his actions*. Here then we have a complete act of reasoning, in which, according to what has been already observed, there are three distinct judgments; two that may be styled previous, inasmuch as they lead to the other, and arise from comparing the middle idea with the two ideas in the question: the third is a consequence of these previous acts, and flows from combining the extreme ideas between themselves. If now we put this reasoning into words, it exhibits what logicians term a syllogism; and, when proposed in due form, runs thus:

“Every creature possessed of reason and liberty is accountable for his actions.”

“Man is a creature possessed of reason and liberty: Therefore man is accountable for his actions.”

V. In this syllogism we may observe, that there are ⁶³ Premises, three several propositions expressing the three judgments implied in the act of reasoning; and so disposed, as to represent distinctly what passes within the mind in tracing the more distant relations of its ideas. The two first propositions answer the two previous judgments in reasoning, and are called the *premises*, because they are placed before the other. The third is termed the *conclusion*, as being gained in consequence of what was asserted in the premises. We are also to remember, that the terms expressing the two ideas whose relations we enquire after, as here *man* and *accountableness*, are in general called the *extremes*; and that the intermediate idea, by means of which the relation is traced, viz. *a creature possessed of reason and liberty*, takes the name of the *middle term*. Hence it follows, that by the *premises* of a syllogism we are always to understand the two propositions where the middle term is severally compared with the *extremes*; for these constitute the previous judgments, whence the truth we are in quest of is by reasoning deduced. The *conclusion* is that other proposition, in which the *extremes* themselves are joined or separated agreeably to what appears upon the above comparison.

VI. The conclusion is made up of the extreme terms ⁶⁴ Major and of the syllogism: and the extreme, which serves as the minor predicate of the conclusion, goes by the name of the *minor term*; the other extreme, which makes the subject in the same proposition, is called the *minor term*. From this distinction of the extremes arises also a distinction between the premises, where these extremes are severally compared with the middle term. That proposition which compares the greater extreme, or the predicate of the conclusion, with the middle term, is called the *major proposition*: the other, wherein the same middle term is compared with the subject of the *conclusion*.

conclusion or lesser extreme, is called the *minor proposition*. All this is obvious from the syllogism already given, where the conclusion is, *Man is accountable for his actions*. For here the predicate *accountable for his actions*, being connected with the middle term in the first of the two premises, *every creature possessed of reason and liberty is accountable for his actions*, gives what we call the *major proposition*. In the second of the premises, *man is a creature possessed of reason and liberty*, we find the lesser extreme, or subject of the conclusion, viz. *man*, connected with the same middle term, whence it is known to be the *minor proposition*. When a syllogism is proposed in due form, the major proposition is always' placed first, the minor next, and the conclusion last.

65
In a single act of reasoning the premises must be intuitive truths.

VII. These things premised, we may in the general define reasoning to be an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known. These previous propositions, in a simple act of reasoning, are only two in number; and it is always required that they be of themselves apparent to the understanding, inasmuch that we assent to and perceive the truth of them as soon as proposed. In the syllogism given above, the premises are supposed to be self-evident truths; otherwise the conclusion could not be inferred by a single act of reasoning. If, for instance, in the major, *every creature possessed of reason and liberty is accountable for his actions*, the connection between the subject and predicate could not be perceived by a bare attention to the ideas themselves; it is evident that this proposition would no less require a proof than the conclusion deduced from it. In this case a new middle term must be sought for, to trace the connection here supposed; and this of course furnishes another syllogism, by which having established the proposition in question, we are then, and not before, at liberty to use it in any succeeding train of reasoning. And should it so happen, that in this second essay there was still some previous proposition whose truth did not appear at first sight, we must then have recourse to a third syllogism, in order to lay open that truth to the mind: because so long as the premises remain uncertain, the conclusion built upon them must be so too. When, by conducting our thoughts in this manner, we at last arrive at some syllogism where the previous propositions are intuitive truths; the mind then rests in full security, as perceiving that the several conclusions it has passed through stand upon the immovable foundation of self-evidence, and when traced to their source terminate in it.

66
Reasoning, in the highest exercise of it, only a concatenation of syllogisms.

VIII. We see, therefore, that in order to infer a conclusion by a single act of reasoning, the premises must be intuitive propositions. Where they are not, previous syllogisms are required; in which case reasoning becomes a complicated act, taking in a variety of successive steps. This frequently happens in tracing the more remote relation of our ideas; where, many middle terms being called in, the conclusion cannot be made out but in consequence of a series of syllogisms following one another in train. But although in this concatenation of propositions, those that form the premises of the last syllogism are often considerably removed from self-evidence; yet if we trace the reasoning backwards, we shall find them the conclusions

of previous syllogisms, whose premises approach nearer and nearer to intuition in proportion as we advance, and are found at last to terminate in it. And if, after having thus unravelled a demonstration, we take it the contrary way; and observe how the mind, setting out with intuitive perceptions, couples them together to form a conclusion; how, by introducing this conclusion into another syllogism, it still advances one step farther; and so proceeds, making every new discovery subservient to its future progress; we shall then perceive clearly, that reasoning, in the highest sense of that faculty, is no more than an orderly combination of those simple acts which we have already so fully explained.

IX. Thus we see, that reasoning, beginning with first principles, rises gradually from one judgement to another, and connects them in such manner, that every stage of the progression brings intuitive certainty along of the progression. And now at length we may clearly understand the definition given above of this distinguishing faculty of the human mind. Reason, we have said, is the ability of deducing unknown truths from principles or propositions that are already known. This evidently appears by the foregoing account, where we see that no proposition is admitted into a syllogism, to serve as one of the previous judgments on which the conclusion rests, unless it is itself a known and established truth, whose connection with self-evident principles has been already traced.

67
Requires intuitive certainty in every step of the progression.

CHAP. II. Of the several kinds of Reasoning; and first, of that by which we determine the Genera and Species of Things.

I. ALL the aims of human reason may in the general be reduced to these two: 1. To rank things under those universal ideas to which they truly belong; and, 2. To ascribe to them their several attributes and properties in consequence of that distribution.

69
Reasoning twofold.

II. One great aim of human reason is to determine the genera and species of things. We have seen in the First Part of this treatise, how the mind proceeds in framing general ideas. We have also seen in the Second Part, how by means of these general ideas we come by universal propositions. Now as in these universal propositions we affirm some property of a genus or species, it is plain that we cannot apply this property to particular objects till we have first determined whether they are comprehended under that general idea of which the property is affirmed. Thus there are certain properties belonging to all even numbers, which nevertheless cannot be applied to any particular number, until we have first discovered it to be of the species expressed by that natural name. Hence reasoning begins with referring things to their several divisions and classes in the scale of our ideas; and as these divisions are all distinguished by particular names, we hereby learn to apply the terms expressing general conceptions to such particular objects as come under our immediate observation.

69
The first kind regards the genera and species of things.
† See Foot-note, p. 195.

III. Now, in order to arrive at these conclusions, by which the several objects of perception are brought under general names, two things are manifestly necessary. First, that we take a view of the idea itself denoted by that general name, and carefully attend to

70
the steps by which we arrive at conclusions of this sort.

the distinguishing marks which serve to characterize it. Secondly, that we compare this idea with the object under consideration, observing diligently whether they agree or differ. If the idea is found to correspond with the particular object, we then without hesitation apply the general name; but if no such correspondence intervenes, the conclusion must necessarily take a contrary turn. Let us, for instance, take the number *eight*, and consider by what steps we are led to pronounce it an *even* number. First then, we call to mind the idea signified by the expression *an even number*, viz. that it is a number divisible into two equal parts. We then compare this idea with the number *eight*, and finding them manifestly to agree, see at once the necessity of admitting the conclusion. These several judgments therefore transferred into language, and reduced to the form of a syllogism, appear thus:

“Every number that may be divided into two equal parts is an *even* number:

“The number *eight* may be divided into two equal parts;

“Therefore the number *eight* is an *even* number.”

71
Those steps
always fol-
lowed, tho'
in familiar
cases we do
not always
attend to
them.

IV. Here it may be observed, that where the general idea, to which particular objects are referred, is very familiar to the mind, and frequently in view; this reference, and the application of the general name, seem to be made without any apparatus of reasoning. When we see a horse in the fields, or a dog in the street, we readily apply the name of the species; habit, and a familiar acquaintance with the general idea, suggesting it instantaneously to the mind. We are not however to imagine on this account that the understanding departs from the usual rules of just thinking. A frequent repetition of acts begets a habit; and habits are attended with a certain promptness of execution, that prevents our observing the several steps and gradations by which any course of action is accomplished. But in other instances, where we judge not by precontracted habits, as when the general idea is very complex, or less familiar to the mind, we always proceed according to the form of reasoning established above. A goldsmith, for instance, who is in doubt as to any piece of metal, whether it be of the species called *gold*, first examines its properties, and then comparing them with the general idea signified by that name, if he finds a perfect correspondence, no longer hesitates under what class of metals to rank it.

72
The great
importance
of this
branch of
reasoning.

V. Nor let it be imagined that our researches here, because in appearance bounded to the imposing of general names upon particular objects, are therefore trivial and of little consequence. Some of the most considerable debates among mankind, and such too as nearly regard their lives, interest, and happiness, turn wholly upon this article. Is it not the chief employment of our several courts of judicature to determine in particular instances, what is law, justice, and equity? Of what importance is it in many cases to decide a-right whether an action shall be termed *murder* or *manslaughter*? We see then that no less than the lives and fortunes of men depend often upon these decisions. The reason is plain. Actions, when once referred to a general idea, draw after them all that may be affirmed of that idea; inasmuch that the determining the species of actions is all one with determining what

proportion of praise or dispraise, commendation or blame, &c. ought to follow them. For as it is allowed that murder deserves death; by bringing any particular action under the head of murder, we of course decide the punishment due to it.

VI. But the great importance of this branch of reason-⁷³ing, and the necessity of care and circumspection And the ex-act obser- in referring particular objects to general ideas, is still vance of it farther evident from the practice of the mathematicians. Every one who has read Euclid knows, that he frequently requires us to draw lines through certain points, and according to such and such directions. The figures thence resulting are often squares, parallelograms, or rectangles. Yet Euclid never supposes this from their bare appearance, but always demonstrates it upon the strictest principles of geometry. Nor is the method he takes in any thing different from that described above. Thus, for instance, having defined a square to be a figure bounded by four equal sides joined together at right angles; when such a figure arises in any construction previous to the demonstration of a proposition, yet he never calls it by that name until he has shown that its sides are equal, and all its angles right ones. Now this is apparently the same form of reasoning we have before exhibited in proving *eight* to be an even number.

VII. Having thus explained the rules by which we⁷⁴ are to conduct ourselves in ranking particular objects Fixed and invariable under general ideas, and shown their conformity to ideas, with the practice and manner of the mathematicians; it remains only to observe, that the true way of rendering this part of knowledge both easy and certain, is, by habituating ourselves to clear and determinate ideas, and keeping them steadily annexed to their respective names. For as all our aim is to apply general words aright, if these words stand for invariable ideas that are perfectly known to the mind, and can be readily distinguished upon occasion, there will be little danger of mistake or error in our reasonings. Let us suppose that, by examining any object, and carrying our attention successively from one part to another, we have acquainted ourselves with the several particulars observable in it. If among these we find such as constitute some general idea, framed and settled beforehand by the understanding, and distinguished by a particular name, the resemblance thus known and perceived necessarily determines the species of the object, and thereby gives it a right to the name by which that species is called. Thus four equal sides, joined together at right angles, make up the notion of a *square*. As this is a fixed and invariable idea, without which the general name cannot be applied; we never call any particular figure a *square* until it appears to have these several conditions; and contrarily, wherever a figure is found with these conditions, it necessarily takes the name of a *square*. The same will be found to hold in all our other reasonings of this kind, where nothing can create any difficulty but the want of settled ideas. If, for instance, we have not determined within ourselves the precise notion denoted by the word *manslaughter*, it will be impossible for us to decide whether any particular action ought to bear that name: because, however nicely we examine the action itself, yet, being strangers to the general idea with which it is to be compared, we are utterly unable

unable to judge of their agreement or disagreement. But if we take care to remove this obstacle, and distinctly trace the two ideas under consideration, all difficulties vanish, and the resolution becomes both easy and certain.

VIII. Thus we see of what importance it is towards the improvement and certainty of human knowledge, that we accustom ourselves to clear and determinate ideas, and a steady application of words.

CHAP. III. Of Reasoning, as it regards the Powers and Properties of Things, and the Relations of our general Ideas.

⁷⁵ The distinction of reasoning, as it regards the sciences and as it concerns common life.

I. WE now come to the second great end which men have in view in their reasonings; namely, the discovering and ascribing to things their several attributes and properties. And here it will be necessary to distinguish between reasoning, as it regards the sciences, and as it concerns common life. In the sciences, our reason is employed chiefly about universal truths, it being by them alone that the bounds of human knowledge are enlarged. Hence the division of things into various classes, called otherwise *genera* and *species*. For these universal ideas being set up as the representatives of many particular things, whatever is affirmed of them may be also affirmed of all the individuals to which they belong. *Murder*, for instance, is a general idea, representing a certain species of human actions. Reason tells us that the punishment due to it is *death*. Hence every particular action, coming under the notion of *murder*, has the punishment of *death* allotted to it. Here then we apply the general truth to some obvious instance; and this is what properly constitutes the reasoning of common life. For men, in their ordinary transactions and intercourse one with another, have, for the most part, to do only with particular objects. Our friends and relations, their characters and behaviour, the constitution of the several bodies that surround us, and the uses to which they may be applied, are what chiefly engage our attention. In all these, we reason about particular things; and the whole result of our reasoning is, the applying the general truths of the sciences in the ordinary transactions of human life. When we see a viper, we avoid it. Wherever we have occasion for the forcible action of water to move a body that makes considerable resistance, we take care to convey it in such a manner that it shall fall upon the object with impetuosity. Now all this happens in consequence of our familiar and ready application of these two general truths. *The bite of a viper is mortal. Water, falling upon a body with impetuosity, acts very forcibly towards setting it in motion.* In like manner, if we set ourselves to consider any particular character, in order to determine the share of praise or dispraise that belongs to it, our great concern is to ascertain exactly the proportion of virtue and vice. The reason is obvious. A just determination, in all cases of this kind, depends entirely upon an application of these general maxims of morality: *Virtuous actions deserve praise; vicious actions deserve blame.*

II. Hence it appears that reasoning, as it regards common life, is no more than the ascribing the general properties of things to those several objects which

which we are more immediately concerned, according as they are found to be of that particular division or class to which the properties belong. The steps then by which we proceed are manifestly these. First, in the reasoning we refer the object under consideration to some general idea or class of things. We then recollect the several attributes of that general idea. And, lastly, ascribe all those attributes to the present object. Thus, in considering the character of *Sempronius*, if we find it to be of the kind called *virtuous*, when we at the same time reflect that a virtuous character is deserving of esteem, it naturally and obviously follows that *Sempronius* is so too. These thoughts put into a *syllogism*, in order to exhibit the form of reasoning here required, run thus:

"Every virtuous man is worthy of esteem.

"*Sempronius* is a virtuous man:

"Therefore *Sempronius* is worthy of esteem."

III. By this *syllogism* it appears, that before we affirm any thing of a particular object, that object must be referred to some general idea. *Sempronius* is pronounced worthy of esteem only in consequence of his being a virtuous man, or coming under that general character of reason. Hence we see the necessary connection of the various parts of reasoning, and the dependence they have one upon another. The determining the genera and species of things is, as we have said, one exercise of human reason; and here we find that this exercise is the first in order, and previous to the other, which consists in ascribing to them their powers, properties, and relations. But when we have taken this previous step, and brought particular objects under general names; as the properties we ascribe to them are no other than those of the general idea, it is plain that, in order to a successful progress in this part of knowledge, we must thoroughly acquaint ourselves with the several relations and attributes of these our general ideas. When this is done, the other part will be easy, and requires scarce any labour or thought, as being no more than an application of the general form of reasoning represented in the foregoing *syllogism*. Now, as we have already sufficiently shown how we are to proceed in determining the genera and species of things, which, as we have said, is the previous step to this second branch of human knowledge; all that is farther wanting towards a due explanation of it is, to offer some considerations as to the manner of investigating the general relations of our ideas. This is the highest exercise of the powers of the understanding, and that by means whereof we arrive at the discovery of universal truths; inasmuch that our deductions in this way constitute that particular species of reasoning which we have before said regards principally the sciences.

IV. But that we may conduct our thoughts with some order and method, we shall begin with observing, that the relations of our general ideas are of two kinds: either such as immediately discover themselves, upon comparing the ideas one with another; or such as, being more remote and distant, require art and contrivance to bring them into view. The relations of the first kind furnish us with intuitive and self-evident truths: those of the second are traced by reasoning, and a due application of intermediate ideas. It is of this last kind that we are to speak here, having

⁷⁶ The steps by which we proceed in the reasoning of common life.

⁷⁷

⁷⁸ Two things required to make a good reasoner.

dis-

dispatched what was necessary with regard to the other in the Second Part. As, therefore, in tracing the more distant relations of things, we must always have recourse to intervening ideas, and are more or less successful in our researches according to our acquaintance with these ideas, and ability of applying them; it is evident that, to make a good reasoner, two things are principally required. *First*, An extensive knowledge of those intermediate ideas, by means of which things may be compared one with another. *Secondly*, The skill and talent of applying them happily in all particular instances that come under consideration.

79
First, an
extensive
knowledge
of interme-
diate ideas.

V. In order to our successful progress in reasoning, we must have an extensive knowledge of those intermediate ideas by means of which things may be compared one with another. For as it is not every idea that will answer the purpose of our inquiries, but such only as are peculiarly related to the objects about which we reason, so as, by a comparison with them, to furnish evident and known truths; nothing is more apparent than that the greater variety of conceptions we can call into view, the more likely we are to find some among them that will help us to the truths here required. And, indeed, it is found to hold in experience, that in proportion as we enlarge our views of things, and grow acquainted with a multitude of different objects, the reasoning faculty gathers strength: for, by extending our sphere of knowledge, the mind acquires a certain force and penetration, as being accustomed to examine the several appearances of its ideas, and observe what light they cast one upon another.

80
To excel
in any one
branch of
learning,
we must be
in general
acquainted
with the
whole circle
of arts and
sciences.

VI. This is the reason why, in order to excel remarkably in any one branch of learning, it is necessary to have at least a general acquaintance with the whole circle of arts and sciences. The truth of it is, all the various divisions of human knowledge are very nearly related among themselves, and, in innumerable instances, serve to illustrate and set off each other. And although it is not to be denied that, by an obstinate application to one branch of study, a man may make considerable progress, and acquire some degree of eminence in it; yet his views will be always narrow and contracted, and he will want that masterly discernment which not only enables us to pursue our discoveries with ease, but also, in laying them open to others, to spread a certain brightness around them. But when our reasoning regards a particular science, it is farther necessary that we more nearly acquaint ourselves with whatever relates to that science. A general knowledge is a good preparation, and enables us to proceed with ease and expedition in whatever branch of learning we apply to. But then, in the minute and intricate questions of any science, we are by no means qualified to reason with advantage until we have perfectly mastered the science to which they belong.

81
Secondly,
the skill of
applying in-
termediate
ideas hap-
pily in par-
ticular in-
stances.

VII. We come now to the second thing required, in order to a successful progress in reasoning; namely, the skill and talent of applying intermediate ideas happily in all particular instances that come under consideration. And here, rules and precepts are of little service. Use and experience are the best instructors. For, whatever logicians may boast of

Nº 186.

being able to form perfect reasoners by book and rule, we find by experience, that the study of their precepts does not always add any great degree of strength to the understanding. In short, it is the habit alone of reasoning that makes a reasoner. And therefore the true way to acquire this talent is, by being much conversant in those sciences where the art of reasoning is allowed to reign in the greatest perfection. Hence it was that the ancients, who so well understood the manner of forming the mind, always began with *mathematics*, as the foundation of their philosophical studies. Here the understanding is by degrees habituated to truth, contracts insensibly a certain fondness for it, and learns never to yield its assent to any proposition but where the evidence is sufficient to produce full conviction. For this reason *Plato* has called mathematical demonstrations the *cathartics* or purgatives of the soul, as being the proper means to cleanse it from error, and restore that natural exercise of its faculties in which just thinking consists.

VIII. If therefore we would form our minds to the habit of reasoning closely and in train, we cannot take any more certain method than the exercising ourselves in mathematical demonstrations, so as to contract a kind of familiarity with them. Not that we look upon it as necessary that all men should be deep mathematicians; but that, having got the way of reasoning which that study necessarily brings the mind to, they may be able to transfer it to other parts of knowledge, as they shall have occasion.

IX. But although the study of mathematics be of all others the most useful to form the mind and give it such an early relish of truth, yet ought not other parts of philosophy to be neglected. For there also we meet with many opportunities of exercising the powers of the understanding; and the variety of subjects naturally leads us to observe all those different turns of thinking that are peculiarly adapted to the several ideas we examine, and the truth we search after. A mind thus trained acquires a certain mastery over its own thoughts, inasmuch that it can range and model them at pleasure, and call such into view as best suit its present designs. Now in this the whole art of reasoning consists; from among a great variety of different ideas to single out those that are most proper for the business in hand, and to lay them together in such order, that from plain and easy beginnings, by gentle degrees, and a continued train of evident truths, we may be insensibly led on to such discoveries, as at our first setting out appeared beyond the reach of human understanding. For this purpose, besides the study of mathematics before recommended, we ought to apply ourselves diligently to the reading of such authors as have distinguished themselves for strength of reasoning, and a just and accurate manner of thinking. For it is observable, that a mind exercised and seasoned to truth, seldom rests satisfied in a bare contemplation of the arguments offered by others; but will be frequently assaying its own strength, and pursuing its discoveries upon the plan it is most accustomed to. Thus we insensibly contract a habit of tracing truth from one stage to another, and of investigating those general relations and properties which we afterwards ascribe to particular things, according as we find them compre-

hended under the abstract ideas to which the properties belong.

CHAP. IV. Of the Forms of Syllogisms.

64
The figures
of syllogisms.

I. HITHERTO we have contented ourselves with a general notion of syllogisms, and of the parts of which they consist. It is now time to enter a little more particularly into the subject, to examine their various forms, and lay open the rules of argumentation proper to each. In the syllogisms mentioned in the foregoing chapters, we may observe, that the *middle term* is the subject of the *major* proposition, and the predicate of the *minor*. This disposition, though the most natural and obvious, is not however necessary; it frequently happening, that the middle term is the subject in both the premises, or the predicate in both; and sometimes, directly contrary to its disposition in the foregoing chapters, the predicate in the major, and the subject in the minor. Hence the distinction of syllogisms into various kinds, called *figures* by logicians. For figure, according to their use of the word, is nothing else but the order and disposition of the middle term in any syllogism. And as this disposition is, we see, fourfold, so the figures of syllogisms thence arising are four in number. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the *first figure*: As,

"No work of God is bad:

"The natural passions and appetites of men are

"the work of God:

"Therefore none of them is bad."

If, on the other hand, it is the predicate of both the premises, the syllogism is said to be the *second figure*: As,

"Whatever is bad is not the work of God:

"All the natural passions and appetites of men

"are the work of God:

"Therefore the natural passions and appetites of

"men are not bad."

Again, in the *third figure*, the middle term is the subject of the two premises: As,

"All Africans are black:

"All Africans are men:

"Therefore some men are black."

And lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the *fourth figure*: As,

"The only being who ought to be worshipped is

"the Creator and Governor of the world:

"The Creator and Governor of the world is

"God:

"Therefore God is the only being who ought to be worshipped."

85
The moods
of syllogisms.

II. But, besides this fourfold distinction of syllogisms, there is also a farther subdivision of them in every figure, arising from the *quantity* and *quality*, as they are called, of the propositions. By quantity we mean the consideration of propositions, as universal or particular; by quality, as affirmative or negative.

Now as, in all the several dispositions of the middle term, the propositions of which a syllogism consists may be either universal or particular, affirmative or

negative; the due determination of these, and so putting them together as the laws of argumentation require, constitute what logicians call the *moods* of syllogisms. Of these moods there is a determinate number to every figure, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

The first figure has only four legitimate moods. The major proposition in this figure must be universal, and the minor affirmative; and it has this property, that it yields conclusions of all kinds, affirmative and negative, universal and particular.

The second figure has also four legitimate moods. Its major proposition must be universal, and one of the premises must be negative. It yields conclusions both universal and particular, but all negative.

The third figure has six legitimate moods. Its minor must always be affirmative; and it yields conclusions both affirmative and negative, but all particular. — These are all the figures which were admitted by the inventor of syllogisms; and of which, so far as we know, the number of legitimate moods has been ascertained, and severally demonstrated. In every figure it will be found upon trial, that there are *sixty-four* different moods of syllogism; and he who thinks it worth while to construct so many in the *fourth figure*, always remembering that the middle term in each must be the predicate of the major and the subject of the minor proposition, will easily discern what number of these moods are legitimate; and give true conclusions.

Besides the rules that are proper to each figure, Aristotle has given some that are common to all, by which the legitimacy of syllogisms may be tried. These may be reduced to five: — 1. There must be only *three terms* in a syllogism: As each term occurs in two of the propositions, it must be precisely the *same in both*; if it be not, the syllogism is said to have *four terms*, which makes a *vicious* syllogism. 2. The middle term must be taken *universally* in one of the premises. 3. Both premises must *not* be *particular* propositions, nor both *negative*. 4. The conclusion must be *particular*, if either of the premises be *particular*; and *negative*, if either of the premises be *negative*. 5. No term can be taken *universally* in the conclusion, if it be not taken *universally* in the premises.

For understanding the *second* and *third* of these rules, it is necessary to observe, that a term is said to be taken *universally*, not only when it is the *subject* of a universal proposition, but also when it is the *predicate* of a negative proposition. On the other hand, a term is said to be taken *particularly*, when it is either the *subject* of a particular or the *predicate* of an affirmative proposition.

III. The division of syllogisms according to mood and figure respects those especially which are known of the other by the name of plain simple syllogisms; that is, which are bounded to three propositions, all simple, and where the extremes and middle term are connected, according to the rules laid down above. But as the mind is not tied down to any one precise form of reasoning, but sometimes makes use of more, sometimes of fewer premises, and often takes in compound and conditional propositions, it may not be amiss to take

notice of the different forms derived from this source, and explain the rules by which the mind conducts itself in the use of them.

87
Conditionals.
sylogisms. IV. When in any syllogism the major is a conditional proposition, the syllogism itself is termed *conditional*. Thus:

"If there is a God, he ought to be worshipped:

"But there is a God:

"Therefore he ought to be worshipped."

In this example, the major, or first proposition, is, we see, conditional, and therefore the syllogism itself is also of the kind called by that name. And here we are to observe, that all conditional propositions are made of two distinct parts: one expressing the condition upon which the predicate agrees or disagrees with the subject, as in this now before us, *if there is a God*; the other joining or disjoining the said predicate and subject, as here, *he ought to be worshipped*. The first of these parts, or that which implies the condition, is called the *antecedent*; the second, where we join or disjoin the predicate and subject, has the name of the *consequent*.

88
Ground of
inference in
conditional
sylogisms. V. In all propositions of this kind, supposing them to be exact in point of form, the relation between the antecedent and consequent must ever be true and real; that is, the antecedent must always contain some certain and genuine condition, which necessarily implies the consequent; for otherwise the proposition itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is assumed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but if we reject the consequent, we are in like manner bound to reject the antecedent. For as the antecedent always expresses some condition which necessarily implies the truth of the consequent; by admitting the antecedent, we allow of that condition, and therefore ought also to admit the consequent. In like manner, if it appears that the consequent ought to be rejected, the antecedent evidently must be so too; because, as was just now demonstrated, the admitting of the antecedent would necessarily imply the admission also of the consequent.

89
The two
moods of
conditional
sylogisms. VI. There are two ways of arguing in *hypothetical* syllogisms, which lead to a certain and unavoidable conclusion. For as the major is always a conditional proposition, consisting of an antecedent and a consequent; if the minor admits the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the *modus ponens*, inasmuch as by it the whole conditional proposition, both antecedent and consequent, is established. Thus:

"If God is infinitely wise, and acts with perfect freedom, he does nothing but what is best:

"But God is infinitely wise, and acts with perfect freedom:

"Therefore he does nothing but what is best."

Here we see the antecedent or first part of the conditional proposition is established in the minor, and the consequent or second part in the conclusion; whence the syllogism itself is an example of the *modus ponens*.

But if now we on the contrary suppose that the minor rejects the consequent, then it is apparent that the conclusion must also reject the antecedent. In this case we are said to argue from the removal of the consequent to the removal of the antecedent, and the particular mood or species of syllogisms thence arising is called by logicians the *modus tollens*; because in it both antecedent and consequent are rejected or taken away, as appears by the following example.

"If God were not a Being of infinite goodness,

"neither would he consult the happiness of his creatures:

"But God does consult the happiness of his creatures:

"Therefore he is a being of infinite goodness.

VII. These two species take in the whole class of ⁹⁰They include all the legitimate ways of arguing. conditional syllogisms, and include all the possible ways of arguing that lead to a legitimate conclusion; because we cannot here proceed by a contrary process of reasoning, that is, from the removal of the antecedent to the removal of the consequent, or from the establishing of the consequent to the establishing of the antecedent. For although the antecedent always expresses some real condition, which, once admitted, necessarily implies the consequent, yet it does not follow that there is therefore no other condition; and if so, then, after removing the antecedent, the consequent may still hold, because of some other determination that infers it. When we say, *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat*; the proposition is certainly true; and, admitting the antecedent, we must also admit the consequent. But as there are other ways by which a stone may gather heat, it will not follow, from the ceasing of the before-mentioned condition, that therefore the consequent cannot take place. In other words, we cannot argue: *But the stone has not been exposed to the rays of the sun; therefore neither has it any degree of heat*: Inasmuch as there are a great many other ways by which heat might have been communicated to it. And if we cannot argue from the removal of the antecedent to the removal of the consequent, no more can we from the admission of the consequent to the admission of the antecedent; because, as the consequent may flow from a great variety of different suppositions, the allowing of it does not determine the precise supposition, but only that some one of them must take place. Thus in the foregoing proposition, *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat*; admitting the consequent, viz. *that it has contracted a certain degree of heat*, we are not therefore bound to admit the antecedent, *that it has been some time exposed to the rays of the sun*; because there are many other causes whence that heat may have proceeded. These two ways of arguing, therefore, hold not in conditional syllogisms.

VIII. As from the major's being a conditional ⁹¹The manner of arguing in disjunctive syllogisms. proposition, we obtain the species of conditional syllogisms; so, where it is a disjunctive proposition, the syllogism to which it belongs is also called *disjunctive*, as in the following example:

"The world is either self-existent, or the work of some finite, or of some infinite Being:

"But

"But it is not self-existent, nor the work of a finite being :

"Therefore it is the work of an infinite Being."

Now, a disjunctive proposition is that, where of several predicates, we affirm one necessarily to belong to the subject, to the exclusion of all the rest, but leave that particular one undetermined. Hence it follows, that as soon as we determine the particular predicate, all the rest are of course to be rejected ; or if we reject all the predicates but one, that one necessarily takes place. When, therefore, in a disjunctive syllogism, the several predicates are enumerated in the major ; if the minor establishes any one of these predicates, the conclusion ought to remove all the rest ; or if, in the minor, all the predicates but one are removed, the conclusion must necessarily establish that one. Thus, in the disjunctive syllogism given above, the major affirms one of the three predicates to belong to the earth, *viz. self-existence, or that it is the work of a finite, or that it is the work of an infinite Being.* Two of these predicates are removed in the minor, *viz. self-existence, and the work of a finite being.* Hence the conclusion necessarily ascribes to it the third predicate, and affirms that it is *the work of an infinite Being.* If now we give the syllogism another turn, inasmuch that the minor may establish one of the predicates, by affirming the earth to be *the production of an infinite Being :* then the conclusion must remove the other two, asserting it to be neither *self-existent, nor the work of a finite being.* These are the forms of reasoning in these species of syllogisms, the justness of which appears at first sight : and that there can be no other, is evident from the very nature of a disjunctive proposition.

92
Imperfect
or mutilated
syllogisms.

IX. In the several kinds of syllogisms hitherto mentioned, we may observe, that the parts are complete ; that is, the three propositions of which they consist are represented in form. But it often happens, that some one of the premises is not only an evident truth, but also familiar and in the minds of all men ; in which case it is usually omitted, whereby we have an imperfect syllogism, that seems to be made up of only two propositions. Should we, for instance, argue in this manner :

"Every man is mortal :

"Therefore every king is mortal."

the syllogism appears to be imperfect, as consisting but of two propositions. Yet it is really complete ; only the minor [*every king is a man*] is omitted : and left to the reader to supply, as being a proposition so familiar and evident that it cannot escape him.

93
Enthymemes.

X. These seemingly imperfect syllogisms are called *enthymemes* ; and occur very frequently in reasoning, especially where it makes a part of common conversation. Nay, there is a particular elegance in them, because, not displaying the argument in all its parts, they leave somewhat to the exercise and invention of the mind. By this means we are put upon exerting ourselves, and seem to share in the discovery of what is proposed to us. Now this is the great secret of fine writing, to frame and put together our thoughts, as to give full play to the reader's imagination, and draw him insensibly into our very views and course of reasoning. This gives a pleasure not unlike to that which the author himself feels in composing. It besides

shortens discourse, and adds a certain force and liveliness to our arguments, when the words in which they are conveyed favour the natural quickness of the mind in its operations, and a single expression is left to exhibit a whole train of thoughts.

XI. But there is another species of reasoning with Ground of reasoning in immediate consequences.
two propositions, which seems to be complete in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind, from which it follows syllogistically. This happens between propositions, where the connection is such, that the admission of the one necessarily and at the first sight implies the admission also of the other. For if it so falls out, that the proposition on which the other depends is self-evident, we content ourselves with barely affirming it, and infer that other by a direct conclusion. Thus, by admitting an universal proposition, we are forced also to admit of all the particular propositions comprehended under it, this being the very condition that constitutes a proposition universal. If then that universal proposition chances to be self-evident, the particular ones follow of course, without any farther train of reasoning. Whoever allows, for instance, *that things equal to one and the same thing are equal to one another*, must at the same time allow, *that two triangles, each equal to a square whose side is three inches, are also equal between themselves.* This argument therefore,

"Things equal to one and the same thing, are equal

"to one another :

"Therefore these two triangles, each equal to the

"square of a line of three inches, are equal between themselves."

is complete in its kind, and contains all that is necessary towards a just and legitimate conclusion. For the first or universal proposition is self-evident, and therefore requires no farther proof. And as the truth of the particular is inseparably connected with that of the universal, it follows from it by an obvious and unavoidable consequence.

XII. Now, in all cases of this kind, where propositions are deduced one from another, on account of a known and evident connection, we are said to reason by immediate consequence. Such a coherence of propositions manifest at first sight, and forcing itself upon the mind, frequently occurs in reasoning. Logicians have explained at some length the several suppositions upon which it takes place, and allow of all immediate consequences that follow in conformity to them. It is however observable, that these arguments, though seemingly complete, because the conclusion follows necessarily from the single proposition that goes before, may yet be considered as real enthymemes, whose major, which is a conditional proposition, is wanting. The syllogism but just mentioned, when represented according to this view, will run as follows :

"If things equal to one and the same thing, are equal to one another ; these two triangles, each equal to a square whose side is three inches, are also equal between themselves.

"But things equal to one and the same thing, are equal to one another :

"Therefore also these triangles, &c. are equal between themselves."

This observation will be found to hold in all immediate

direct consequences whatsoever, inasmuch that they are in fact no more than enthymemes of hypothetical syllogisms. But then it is particular to them, that the ground on which the conclusion rests, namely its coherence with the minor, is of itself apparent, and seen immediately to flow from the rules and reasons of logic.

56
A series of
plain simple
syllogisms.

XIII. The next species of reasoning we shall take notice of here is what is commonly known by the name of a *series*. This is a way of arguing, in which a great number of propositions are so linked together, that the predicate of one becomes continually the subject of the next following, until at last a conclusion is formed, by bringing together the subject of the first proposition, and the predicate of the last. Of this kind is the following argument.

"God is omnipotent :

"An omnipotent being can do every thing possible :

"He that can do every thing possible, can do whatever involves not a contradiction :

"Therefore God can do whatever involves not a contradiction."

This particular combination of propositions may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests. The reason is, because the series itself may be resolved into as many simple syllogisms as there are middle terms in it; where this is found universally to hold, that when such a resolution is made, and the syllogisms are placed in train, the conclusion of the last in the series is also the conclusion of the series. This kind of argument, therefore, as it serves to unite several syllogisms into one, must stand upon the same foundation with the syllogisms of which it consists, and is indeed, properly speaking, no other than a compendious way of reasoning syllogistically.

97
A series of
hypothetical
syllogisms.

XIV. What is here said of plain simple propositions may be as well applied to those that are conditional; that is, any number of them may be so joined together in a series, that the consequent of one shall become continually the antecedent of the next following; in which case, by establishing the antecedent of the first proposition, we establish the consequent of the last, or by removing the last consequent remove also the first antecedent. This way of reasoning is exemplified in the following argument.

"If we love any person, all emotions of hatred towards him cease :

"If all emotions of hatred towards a person cease, we cannot rejoice in his misfortunes :

"If we rejoice not in his misfortunes, we certainly wish him no injury :

"Therefore, if we love a person, we wish him no injury."

It is evident that this series, as well as the last, may be resolved into a series of distinct syllogisms, with this only difference, that here the syllogisms are all conditional.

98
The ground
of argu-
mentation
in a dilem-
ma.

XV. The last species of syllogism we shall take notice of in this chapter is that commonly distinguished by the name of a *dilemma*. A dilemma is an argument by which we endeavour to prove the absurdity or falsehood of some assertion. In order to this, we assume a conditional proposition, the antecedent

of which is the assertion to be disproved, and the consequent a disjunctive proposition, enumerating all the possible suppositions upon which that assertion can take place. If then it appears, that all these several suppositions ought to be rejected, it is plain, that the antecedent or assertion itself must be so too. When therefore such a proposition as that before mentioned is made the major of any syllogism; if the minor rejects all the suppositions contained in the consequent, it follows necessarily, that the conclusion ought to reject the antecedent, which, as we have said, is the very assertion to be disproved. This particular way of arguing is that which logicians call a *dilemma*; and from the account here given of it, it appears that we may in the general define it to be a hypothetical syllogism, where the consequent of the major is a disjunctive proposition, which is wholly taken away or removed in the minor. Of this kind is the following :

"If God did not create the world perfect in its

"kind, it must either proceed from want of inclination, or from want of power :

"But it could not proceed either from want of inclination, or from want of power :

"Therefore, he created the world perfect in its kind." Or, which is the same thing : "It is absurd to say that he did not create the world perfect in its kind."

XVI. The nature then of a dilemma is universally this. The major is a conditional proposition, whose consequent contains all the several suppositions upon which the antecedent can take place. As therefore these suppositions are wholly removed in the minor, it is evident that the antecedent must be so too; inasmuch that we here always argue from the removal of the consequent to the removal of the antecedent. That is, a dilemma is an argument in the *modus tollens* of hypothetical syllogisms, as logicians love to speak. Hence it is plain, that if the antecedent of the major is an affirmative proposition, the conclusion of the dilemma will be negative; but if it is a negative proposition, the conclusion will be affirmative.

CHAP. V. Of Induction.

I. ALL reasoning proceeds ultimately from first truths, either self-evident or taken for granted; and the first truths of syllogistic reasonings are general propositions. But except in the mathematics, and such other sciences as, being conversant about mere ideas, have no immediate relation to things without the mind, we cannot assume as truths propositions which are general. The mathematician indeed may be considered as taking his ideas from the beginning in their general form. Every proposition composed of such ideas is therefore general; and those which are theoretic are reducible to two parts, or terms, a predicate and a subject, with a copula generally affirmative. If the agreement or the relation between the two terms be not immediate and self-evident, he has recourse to an *axiom*, which is a proposition still more general, and which supplies him with a third or middle term. This he compares first with the predicate, and then with the subject, or vice versa. These two comparisons, when drawn out in form, make two propositions,

positions, which are called the *premises*; and if they happen to be *immediate* and *self-evident*, the *conclusion*, consisting of the terms of the question proposed, is said to be demonstrated. This method of reasoning is conducted exactly in the syllogistic form explained in the preceding chapter.

II. But in sciences which treat of things external to the mind, we cannot assume as *first principles* the most general propositions, and from them infer others less and less general till we descend to particulars. The reason is obvious. Every thing in the universe, whether of mind or body, presents itself to our observation in its individual state; so that *perception* and *judgment* employed in the investigation of truth, whether *physical*, *metaphysical*, *moral*, or *historical*, have in the first place to encounter with *PARTICULARS*. "With these reason begins, or should begin, its operations. It observes, tries, canvasses, examines, and compares them together, and judges of them by some of those native evidences and original lights which, as they are the first and indispensable inlets of knowledge to the mind, have been called the *primary principles of truth*. See *METAPHYSICS*.

101
From which, by induction, it ascends to generals or axioms.

III. "By such acts of observation and judgment, diligently practised and frequently repeated, on many *instances* of the same class or of a similar nature, noting their agreements, marking their differences however minute, and rejecting all instances which, however similar in appearance, are not in effect the same, *REASON*, with much labour and attention, extracts some *general laws* respecting the powers, properties, qualities, actions, passions, virtues, and relations of *real things*. This is no hasty, premature, *notional* abstraction of the mind, by which images and ideas are formed that have no archetypes in nature: it is a rational, operative, experimental process, instituted and executed upon the constitution of beings, which in part compose the universe. By this process *REASON* advances from *particulars* to *generals*, from *less general* to *more general*, till by a series of flow progression, and by regular degrees, it arrive at the *most general* notions, called *FORMS* or *FORMAL CAUSES* (c). And by *affirming* or *denying* a genus of a species, or an accident of a substance or class of substances, through all the stages of the gradation, we form

conclusions, which, if logically drawn, are *AXIOMS* (d) or general propositions ranged one above another, till they terminate in those that are *UNIVERSAL*.

102

IV. "Thus, for instance, the *evidence of the external senses* is obviously the *PRIMARY PRINCIPLE* from which all physical knowledge is derived. But, whereas nature begins with *causes*, which, after a variety of changes, produce *effects*, the senses open upon the *effects*, and from them, through the slow and painful road of experiment and observation, ascend to *causes*. By experiments and observations skillfully chosen, artfully conducted, and judiciously applied, the philosopher advances from one stage of inquiry to another in the rational investigation of the general *causes* of physical truth. From different experiments and observations made on the same individual subject, and from the same experiments and observations made on different subjects of the same kind, by comparing and judging, he discovers some *qualities*, *causes*, or *phenomena*, which, after carefully distinguishing and rejecting all contradictory instances that occur, he finds common to many. Thus, from many collateral comparisons and judgments formed upon *particulars*, he ascends to *generals*; and by a repetition of the same industrious process and laborious investigation, he advances from *general* to *more general*, till at last he is enabled to form a few of the *most general*, with their attributes and operations, into *AXIOMS* or *secondary principles*, which are the well-founded laws enacted and enforced by the God of nature.—This is that just and philosophic method of reasoning which sound logic precribes in this as well as in other parts of learning; by which, through the slow but certain road of experiment and observation, the mind ascends from appearances to qualities, from effects to causes, and from experiments upon many particular subjects forms *general propositions* concerning the powers and properties of physical body.

103

V. "AXIOMS so investigated and established are applicable to all parts of learning, and are the indispensable, and indeed the wonderful expedients, by which, in every branch of knowledge, reason pushes on its inquiries in the particular pursuit of truth: and the method of reasoning by which they are formed, is that of true and legitimate *INDUCTION*; which is therefore by

Lord

AXIOMS, so established, applicable in all parts of learning.

(c) Qui FORMAS novit, is, quæ adhuc non facta sunt, qualia nec naturæ vicissitudines, nec experimentales induitrix unquam in ætuum produxissent, nec cogitationem humanam subituræ fuissent, detegit et educit. *Baconi Nov. Org.*

(d) The word axiom ἀξίωμα literally signifies *dignity*: Hence it is used metaphorically to denote a *general truth* or *maxim*, and sometimes any truth that is *self-evident*, which is called a *dignity* on account of its importance in a process of reasoning. The axioms of Euclid are propositions extremely general; and so are the axioms of the Newtonian philosophy. But these two kinds of axioms have very different origins. The former appear true upon a bare contemplation of our ideas; whereas the latter are the result of the most laborious induction. Lord Bacon therefore strenuously contends that they should never be taken upon conjecture, or even upon the authority of the learned; but that, as they are the general principles and grounds of all learning, they should be canvassed and examined with the most scrupulous attention, "ut axiomatum corrigatur iniquitas, quæ plerumque in exemplis vulgaris fundamentum habent:" *De Augm. Sc.* lib. ii. cap. 2. "Atque illa ipsa putativa principia ad rationes reddendas compellere decrevimus, quousque plane constaret." *Distrib. Operis*.—Dr Tatnam makes a distinction between axioms *intuitive* and axioms *self-evident*. *Intuitive axioms*, according to him, pass through the first inlets of knowledge, and flash direct conviction on the minds, as external objects do on the senses, of all men. Other axioms, though not intuitive, may be properly said to be *self-evident*; because, in their formation, reason judges by single comparisons without the help of a third idea or middle term; so that they have their evidence in themselves, and though inductively framed they cannot be syllogistically proved. Is this distinction be just, and we think it is; only *particular truths* can be intuitive axioms.

Lord Bacon, the best and foundest of logicians, called the *key of interpretation*.

VI. "Instead of taking his axioms arbitrarily out of the great families of the categories (see CATEGORY), and erecting them by his own sophistical invention into the principles upon which his disputation was to be employed, had the analytical genius of Aristotle presented us with the laws of the true *INDUCTIVE LOGIC*, by which *AXIOMS* are philosophically formed, and had he with his usual sagacity given us an example of it in a single branch of science; he would have brought to the temple of truth an offering more valuable than he has done by the aggregate of all his logical and philosophical productions.

VII. "In all sciences, except the mathematics, it is only after the *INDUCTIVE* process has been industriously pursued and successfully performed, that *DEFINITION* may be logically and usefully introduced, by beginning with the *genus*, passing through all the graduate and subordinate stages, and marking the *specific difference* as it descends, till it arrive at the *individual*, which is the subject of the question. And by adding an *affirmation* or *negation* of the attribute of the *genus* on the *species* or *individual*, or of a general *accident* on the particular *substance* so defined, making the definition a proposition, the truth of the question will be logically solved without any farther process. So that instead of being the *first*, as employed by the logic in common use, *definition* may be the *last* act of reason in the search of truth in general.

VIII. "These *AXIOMS* or general propositions, thus inductively established, become another species of *PRINCIPLES*, which may be properly called *SECONDARY*, and which lay the foundation of the syllogistic method of reasoning. When these are formed, but not before, we may safely admit the maxim with which logicians set out in the exercise of their art, as the great hinge on which their reasoning and disputation turn: *From truths that are already known, to derive others which are not known*. Or, to state it more comprehensively, so as to apply to probable as well as to scientific reasoning—*From truths which are better known, to derive others which are less known*. Philosophically speaking, syllogistic reasoning is, under general propositions to reduce others which are less general or which are particular; for the inferior ones are known to be true, only as we trace their connection with the superior. Logically speaking, it is, To predicate a *genus* of a *species* or *individual* comprehended under it, or an *accident* of the *substance* in which it is inherent.

IX. "Thus *INDUCTION* and *SYLLOGISM* are the two methods of *direct reasoning* corresponding to the two kinds of principles, *primary* and *secondary*, on which they are founded, and by which they are respectively conducted. In both methods, indeed, reason proceeds by *judging* and *comparing*, but the process is different throughout; and though it may have the sanction of Aristotle, an *inductive syllogism* is a solecism.

X. "Till general truths are ascertained by induction, the *third* or *middle terms* by which syllogisms are

made are no where safely to be found. So that another position of the Stagyrice, that *syllogism is naturally prior in order to induction*, is equally unfounded; for *induction* does not only naturally but necessarily precede *syllogism*; and, except in mathematics, is in every respect indispensable to its existence; since, till generala are established, there can be neither *definition*, *proposition*, nor *axiom*, and of course no syllogism. And as induction is the first, so is it the more *essential* and fundamental instrument of reasoning: for as syllogism cannot produce its own *principles*, it must have them from induction; and if the general propositions or secondary principles be imperfectly or infernally established, and much more if they be taken at hazard, upon authority, or by arbitrary assumption like those of Aristotle, all the syllogising in the world is a vain and useless logomachy, only instrumental to the multiplication of false learning, and to the invention and confirmation of error. The truth of syllogisms depends ultimately on the truth of axioms, and the truth of axioms on the soundness of inductions (x)."—But though induction is prior in order, as well as superior in utility, to syllogism, we have here treated it expedient to treat of it last; both because syllogism is an easier exercise of the reasoning faculty than induction, and because it is the method of mathematics, the first science of reason in which the student is commonly initiated.

CHAP. VI. Of Demonstration.

I. HAVING dispatched what seemed necessary to be said with regard to the two methods of direct reasoning, *induction* and *syllogism*; we now proceed to consider the laws of demonstration. And here it must be acknowledged, that in strict demonstration, which removes from the mind all possibility of doubt or error, the inductive method of reasoning can have no place. When the experiments and observations from which the general conclusion is drawn are numerous and extensive, the result of this mode of reasoning is moral certainty; and could the induction be made complete, it would be absolute certainty, equally convincing with mathematical demonstration. But however numerous and extensive the observations and experiments may be upon which an inductive conclusion is established, they must of necessity come short of the number and extent of nature; which, in some cases, by its immensity, will defeat all possibility of their co-extension; and in others, by its distance, lies out of the reach of their immediate application. Though truth does not appear in all other departments of learning with that bold and resistless conviction with which it prevails in the mathematical science, it shines through them all, if not interrupted by prejudice or perverted by error, with a clear and useful, though inferior strength. And as it is not necessary for the general safety or convenience of a traveller, that he should always enjoy the heat and splendor of a mid-day sun, whilst he can with more ease pursue his journey under the weaker influence of a morning or an evening ray; so it is not requisite, for the various concerns and purposes

(x) This chapter is almost wholly taken from *Tatham's Chart and Scale of Truth*; a work which, notwithstanding the ruggedness of its style, has so much real merit as a system of logic, that it cannot be too diligently studied by the young inquirer who wishes to travel by the straight road to the temple of Science.

poses of life, that men should be led by truth of the most redundant brightness. Such truth is to be had only in those sciences which are conversant about ideas and their various relations; where every thing being certainly what it appears to be, definitions and axioms arise from mere intuition. Here *sylogism* takes up the process from the beginning; and by a sublime intellectual motion advances from the simplest axioms to the most complicated speculations, and exhibits truth springing out of its first and purest elements, and spreading on all sides into a system of science. As each step in the progress is syllogistic, we shall endeavour to explain the use and application of syllogisms in this species of reasoning.

209
Of reasoning by a concatenation of syllogisms.

We have seen, that in all the different appearances they put on, we still arrive at a just and legitimate conclusion; now it often happens, that the conclusion of one syllogism becomes a previous proposition in another; by which means great numbers of them are sometimes linked together in a series, and truths are made to follow one another in train. And as in such a concatenation of syllogisms all the various ways of reasoning that are truly conclusive may be with safety introduced; hence it is plain, that in deducing any truth from its first principles, especially where it lies at a considerable distance from them, we are at liberty to combine all the several kinds of syllogisms above explained, according as they are found best to suit the end and purpose of our inquiries. When a proposition is thus, by means of syllogisms, collected from others more evident and known, it is said to be *proved*; so that we may in the general define the proof of a proposition to be a syllogism, or series of syllogisms, collecting that proposition from known and evident truths. But more particularly, if the syllogisms of which the proofs consist admit of no premises but definitions, self-evident truths, and propositions already *demonstrated*, then is the argument so constituted called a *demonstration*; whereby it appears that demonstrations are ultimately founded on definitions and self-evident propositions.

210
All syllogisms whatsoever reducible to the first figure.

II. All syllogisms whatsoever, whether compound, multiform, or defective, are reducible to plain simple syllogisms in some one of the four figures. But this is not all. Syllogisms of the first figure, in particular, admit of all possible conclusions: that is, any propositions whatsoever, whether an universal affirmative or universal negative, a particular affirmative or particular negative, which fourfold division embraces all their varieties; any one of these may be inferred by virtue of some syllogism in the first figure. By this means it happens that the syllogisms of all the other figures are reducible also to syllogisms of the first figure, and may be considered as standing on the same foundation with them. We cannot here demonstrate and explain the manner of this reduction, because it would too much swell the bulk of this treatise. It is enough to take notice that the thing is universally known and allowed among logicians, to whose writings we refer such as desire farther satisfaction in this matter. This then being laid down, it is plain that any demonstration whatsoever may be considered as composed of a series of syllogisms, all in the first figure. For, since all the syllogisms that enter the demonstration are reducible to syllogisms of some one of the four figures; and since the syllogisms of all the

other figures are farther reducible to syllogisms of the first figure, it is evident, that the whole demonstration may be resolved into a series of these last syllogisms. Let us now, if possible, discover the ground upon which the conclusion rests in syllogisms of the first figure; because, by so doing, we shall come at an universal principle of certainty, whence the evidence of all demonstrations in all their parts may be ultimately derived.

III. The rules then of the first figure are briefly these. The middle term is the subject of the major proposition, and the predicate of the minor. The major is always an universal proposition, and the minor always affirmative. Let us now see what effect these rules will have in reasoning. The major is an universal proposition, of which the middle term is the subject, and the predicate of the conclusion the predicate. Hence it appears, that in the major the predicate of the conclusion is always affirmed or denied universally of the middle term. Again the minor is an affirmative proposition, whereof the subject of the conclusion is the subject, and the middle term the predicate. Here then the middle term is affirmed of the subject of the conclusion; that is, the subject of the conclusion is affirmed to be comprehended under, or to make a part of, the middle term. Thus then we see what is done in the premises of a syllogism of the first figure. The predicate of the conclusion is universally affirmed or denied of some idea. The subject of the conclusion is affirmed to be or to make a part of that idea. Hence it naturally and unavoidably follows, that the predicate of the conclusion ought to be affirmed or denied of the subject. To illustrate this by an example, we shall resume one of the syllogisms of the first chapter.

"Every creature possessed of reason and liberty is accountable for his actions:

"Man is a creature possessed of reason and liberty: Therefore man is accountable for his actions."

Here, in the first proposition, the predicate of the conclusion, *accountableness*, is affirmed of all creatures that have reason and liberty. Again, in the second proposition, *man*, the subject of the conclusion, is affirmed to be or to make a part of this class of creatures. Hence the conclusion necessarily and unavoidably follows, *viz.* that man is accountable for his actions; because, if reason and liberty be that which constitutes a creature accountable, and man has reason and liberty, it is plain he has that which constitutes him accountable. In like manner, where the major is a negative proposition, or denies the predicate of the conclusion universally of the middle term, as the minor always asserts the subject of the conclusion to be or make a part of that middle term, it is no less evident that the predicate of the conclusion ought in this case to be denied of the subject. So that the ground of reasoning, in all syllogisms of the first figure, is manifestly this: "Whatever may be affirmed universally of any idea, may be affirmed of every or any number of particulars comprehended under that idea." And again: "Whatever may be denied universally of any idea, may be in like manner denied of every or any number of its individuals." These two propositions are called by logicians the *dictum de omni*, and *dictum de nullo*; and are indeed the great principles

principles of syllogistic reasoning, inasmuch as all conclusions whatsoever either rest immediately upon them, or upon propositions deduced from them. But what adds greatly to their value is, that they are really self-evident truths, and such as we cannot gain say without running into an express contradiction. To affirm, for instance, that *no man is perfect*, and yet argue that *some men are perfect*; or to say that *all men are mortal*, and yet that *some men are not mortal*, is to assert a thing to be and not to be at the same time.

112
Demonstration an infallible guide to truth and certainty.

IV. And now we may affirm, that, in all syllogisms of the first figure, if the premises are true, the conclusion must needs be true. If it be true that the predicate of the conclusion, whether affirmative or negative, agrees universally to some idea; and if it be also true that the subject of the conclusion is a part of or comprehended under that idea; then it necessarily follows, that the predicate of the conclusion agrees also to the subject. For to assert the contrary, would be to run counter to some one of the two principles before established; that is, it would be to maintain an evident contradiction. And thus we are come at last to the point we have been all along endeavouring to establish; namely, that every proposition which can be demonstrated is necessarily true. For as every demonstration may be resolved into a series of syllogisms all in the first figure; and as in any one of these syllogisms, if the premises are true, the conclusion must needs be so too; it evidently follows, that if all the several premises are true, all the several conclusions are so, and consequently the conclusion also of the last syllogism, which is always the proposition to be demonstrated. Now that all the premises of a demonstration are true, will easily appear from the very nature and definition of that form of reasoning. A demonstration, as we have said, is a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. Definitions are identical propositions, wherein we connect the description of an idea with the name by which we choose to have that idea called, and therefore as to their truth there can be no dispute. Self-evident propositions appear true of themselves, and leave no doubt or uncertainty in the mind. Propositions, before established, are no other than conclusions gained by one or more steps from definitions and self-evident principles, that is, from true premises, and therefore must needs be true. Whence all the previous propositions of a demonstration being, we see, manifestly true; the last conclusion, or proposition to be demonstrated, must be so too. So that demonstration not only leads to certain truth, but we have here also a clear view of the ground and foundation of that certainty. For as, in demonstrating, we may be said to do nothing more than combine a series of syllogisms together, all resting on the same bottom; it is plain that one uniform ground of certainty runs through the whole, and that the conclusions are every where built upon some one of the two principles before established, as the foundation of all our reasoning. These two principles are easily reduced into one, and may be expressed thus: "Whatever predicate, whether affirmative or negative, agrees universally to any idea; the same must needs agree to every or any number of individuals comprehended under that idea." And

thus at length we have, according to our first design, reduced the certainty of demonstration to one simple and universal principle; which carries its own evidence along with it, and which is indeed the ultimate foundation of all syllogistic reasoning.

V. Demonstration therefore serving as an infallible guide to truth, and standing on so sure and unalterable a basis, we may now venture to assert, that the rules of logic furnish a sufficient criterion for the distinguishing between truth and falsehood. For since every proposition that can be demonstrated is necessarily true, he is able to distinguish truth from falsehood who can with certainty judge when a proposition is truly demonstrated. Now, a demonstration is, as we have said, nothing more than a concatenation of syllogisms, all whose premises are definitions, self-evident truths, or propositions previously established. To judge therefore of the validity of a demonstration, we must be able to distinguish whether the definitions that enter it are genuine, and truly descriptive of the ideas they are meant to exhibit: whether the propositions assumed without proofs as intuitive truths have really that self-evidence to which they lay claim: whether the syllogisms are drawn up in due form, and agreeable to the laws of argumentation: in fine, whether they are combined together in a just and orderly manner, so that no demonstrable propositions serve any where as premises unless they are conclusions of previous syllogisms. Now, it is the business of logic, in explaining the several operations of the mind, fully to instruct us in all these points. It teaches the nature and end of definitions, and lays down the rules by which they ought to be framed. It unfolds the several species of propositions, and distinguishes the self-evident from the demonstrable. It delineates also the different forms of syllogisms, and explains the laws of argumentation proper to each. In fine, it describes the manner of combining syllogisms, so as that they may form a train of reasoning, and lead to the successive discovery of truth. The precepts of logic, therefore, as they enable us to judge with certainty when a proposition is duly demonstrated, furnish a sure criterion for the distinguishing between truth and falsehood.

VI. Perhaps it may be objected, that demonstration is a thing very rare and uncommon, as being the prerogative of but a few sciences, and therefore the criterion here given can be of no great use. But where 3

proof, and of what is still wanting to render it full and complete, enable us to make a due estimate of the measures of probability, and to proportion our assent to the grounds on which the proposition stands. And this is all we can possibly arrive at, or even so much as hope for, in the exercise of faculties so imperfect and limited as ours.

¹¹⁵ The distinction of demonstration into direct and indirect.
 VII. Before we conclude this chapter, it may not be improper to take notice of the distinction of demonstration into *direct* and *indirect*. A *direct demonstration* is, when, beginning with definitions, self-evident propositions, or known and allowed truths, we form a train of syllogisms, and combine them in an orderly manner, continuing the series through a variety of successive steps, until at last we arrive at a syllogism whose conclusion is the proposition to be demonstrated. Proofs of this kind leave no doubt or uncertainty behind them; because, all the several premises being true, the conclusions must be so too, and of course the very last conclusion or proposition to be proved. The other species of demonstration is the *indirect*, or, as it is sometimes called, the *apagogical*. The manner of proceeding here is, by assuming a proposition which directly contradicts that we mean to demonstrate; and thence, by a continued train of reasoning, in the way of a direct demonstration, deducing some absurdity or manifest untruth. For hereupon we conclude, that the proposition assumed was false; and thence again, by an immediate consequence, that the proposition to be demonstrated is true. Thus Euclid, in his third book, being to demonstrate that *circles which touch one another inwardly have not the same centre*, assumes the direct contrary to this, *viz. that they have the same centre*; and thence, by an evident train of reasoning, proves that *a part is equal to the whole*. The supposition therefore leading to this absurdity he concludes to be false, *viz. that circles touching one another inwardly have the same centre*; and thence again immediately infers, that *they have not the same centre*.

¹¹⁶ Ground of reasoning in indirect demonstration.
 VIII. Now, because this manner of demonstration is accounted by some not altogether so clear and satisfactory, we shall therefore endeavour to show, that it equally with the other leads to truth and certainty. Two propositions are said to be *contradictory* one of another, when that which is asserted to be in the one is asserted not to be in the other. Thus the propositions, *Circles that touch one another inwardly have the same centre*, and *Circles that touch one another inwardly have not the same centre*, are contradictory, because the second asserts the direct contrary of what is asserted in the first. Now, in all contradictory propositions, this holds universally, That one of them is necessarily true, and the other necessarily false. For if it be true, that circles which touch one another inwardly have not the same centre; it is unavoidably false, that they have the same centre. On the other hand, if it be false that they have the same centre, it is necessarily true that they have not the same centre. Since therefore it is impossible for them to be both true or both false at the same time; it unavoidably follows, that one is necessarily true, and the other necessarily false. This then being allowed, which is indeed self-evident; if any two contradictory propositions are assumed, and one of them can by a clear train of reasoning be demonstrated to be false, it necessarily follows that the other is

true. For as the one is necessarily true, and the other necessarily false; when we come to discover which is the false proposition, we thereby also know the other to be true.

¹¹⁷ Indirect demonstrations are a sure guide to certainty.
 IX. Now this is precisely the manner of an indirect demonstration, as is evident from the account given of it above. For there we assume a proposition which directly contradicts that we mean to demonstrate; and, having by a continued series of proofs shown it to be false, thence infer that its contradictory, or the proposition to be demonstrated is true. As, therefore, this last conclusion is certain and unavoidable; let us next inquire after what manner we come to be satisfied of the falsehood of the assumed proposition, that so no possible doubt may remain as to the force and validity of demonstrations of this kind. The manner then is plainly this: Beginning with the assumed proposition, we, by the help of definitions, self-evident truths, or propositions already established, continue a series of reasoning, in the way of a direct demonstration, until at length we arrive at some absurdity or known falsehood. Thus Euclid, in the example before-mentioned, from the supposition that circles touching one another inwardly have the same centre, deduces, that *a part is equal to the whole*. Since, therefore, by a due and orderly process of reasoning, we come at last to a false conclusion; it is manifest, that all the premises cannot be true: for, were all the premises true, the last conclusion must be so too, by what has been before demonstrated. Now, as to all the other premises made use of in the course of reasoning, they are manifest and known truths by supposition, as being either definitions, self-evident propositions, or truths previously established. The assumed proposition is that only as to which any doubt or uncertainty remains. That alone, therefore, can be false; and indeed, from what has been already shown, must unavoidably be so. And thus we see, that in indirect demonstrations, two contradictory propositions being laid down, one of which is demonstrated to be false, the other, which is always the proposition to be proved, must necessarily be true; so that here, as well as in the direct way of proof, we arrive at a clear and satisfactory knowledge of truth.

¹¹⁸ A particular case of indirect demonstration.
 X. This is universally the method of reasoning in all apagogical or indirect demonstrations. But if any proposition is assumed, from which, in a direct train of reasoning, we can deduce its contradictory; the proposition so assumed is false, and the contradictory one true. For if we suppose the assumed proposition to be true, then, since all the other premises that enter the demonstration are also true, we shall have a series of reasoning consisting wholly of true premises; whence the last conclusion or contradictory of the assumed proposition must be true likewise: so that by this means we should have two contradictory propositions both true at the same time, which is manifestly impossible. The assumed proposition, therefore, whence this absurdity flows, must necessarily be false; and consequently its contradictory, which is here the proposition deduced from it, must be true. If then any proposition is proposed to be demonstrated, and we assume the contradictory of that proposition, and thence directly infer the proposition to be demonstrated; by this very means we know that the proposition so inferred,

ferred is true. For, since from an assumed proposition we have deduced its contradictory, we are thereby certain that the assumed proposition is false; and if so, then its contradictory, or that deduced from it, which in this case is the same with the proposition to be demonstrated, must be true.

119
A due knowledge of the principles of logic indispensably necessary to make us proper judges of demonstration.

XI. We have a curious instance of this in the twelfth proposition of the ninth book of the Elements. Euclid there proposes to demonstrate, that in any series of numbers, rising from unity in geometrical progression, all the prime numbers that measure the last term in the series will also measure the next after unity. In order to this, he assumes the contradictory of the proposition to be demonstrated; namely, that some prime number measuring the last term in the series does not measure the next after unity; and thence, by a continued train of reasoning, proves that it actually does measure it. Hereupon he concludes the assumed proposition to be false; and that which is deduced from it, or its contradictory, which is the very proposition he proposed to demonstrate, to be true. Now that this is a just and conclusive way of reasoning, is abundantly manifest from what we have so clearly established above. Whence it appears, how necessary some knowledge of the rules of logic is, to enable us to judge of the force, justness, and validity, of demonstrations. For, though it is readily allowed, that by the mere strength of our natural faculties we can at once discern, that of two contradictory propositions, the one is necessarily true, and the other necessarily false; yet

when they are so linked together in a demonstration, as that the one serves as a previous proposition whence the other is deduced, it does not so immediately appear, without some knowledge of the principles of logic, why that alone, which is collected by reasoning, ought to be embraced as true, and the other, whence it is collected, to be rejected as false.

XII. Having thus sufficiently evinced the certainty of demonstration in all its branches, and shown the rules by which we ought to proceed, in order to arrive at a just conclusion, according to the various ways of arguing made use of; it is needless to enter upon a particular consideration of those several species of false reasoning which logicians distinguish by the name of *sophisms*. He that thoroughly understands the form and structure of a good argument, will of himself readily discern every deviation from it. And although *sophisms* have been divided into many classes, which are all called by sounding names, that therefore carry in them much appearance of learning; yet are the errors themselves so very palpable and obvious, that it would be lost labour to write for a man capable of being misled by them. Here, therefore, we choose to conclude this part of logic; and shall in the next give some account of *Method*: which, though inseparable from reasoning, is nevertheless always considered by logicians as a distinct operation of the mind; because its influence is not confined to the mere exercise of the reasoning faculty, but extends in some degree to all the transactions of the understanding.

PART IV. OF METHOD.

121
The understanding sometimes employed in putting together known truths.

WE have now done with the three first operations of the mind, whose office it is to search after truth, and enlarge the bounds of human knowledge. There is yet a fourth, which regards the disposal and arrangement of our thoughts, when we endeavour so to put them together as that their mutual connection and dependence may be clearly seen. This is what logicians call *Method*, and place always the last in order in explaining the powers of the understanding; because it necessarily supposes a previous exercise of our other faculties, and some progress made in knowledge before we can exert it in any extensive degree.

122
Sometimes in the search and discovery of such as are unknown.

II. In this view, it is plain that we must be beforehand well acquainted with the truths we are to combine together; otherwise, how could we discern their several connections and relations, or so dispose of them as their mutual dependence may require? But it often happens, that the understanding is employed, not in the arrangement and composition of known truths, but in the search and discovery of such as are unknown. And here the manner of proceeding is very different. We assemble at once our whole stock of knowledge relating to any subject, and, after a general survey of things, begin with examining them separately and by parts. Hence it comes to pass, that whereas, at our first setting out, we were acquainted only with some of the grand strokes and outlines of truth; by thus pursuing her through her several windings and recesses, we gradually discover those more inward and finer touches whence she derives all her strength, symmetry, and beauty. And here it

is, that when, by a narrow scrutiny into things, we have unravelled any part of knowledge, and traced it to its first and original principles, inasmuch that the whole frame and contexture of it lies open to the view of the mind; here it is, that, taking it the contrary way, and beginning with these principles, we can so adjust and put together the parts as the order and method of science requires.

III. But as these things are best understood when illustrated by examples; let us suppose any machine, for instance a watch, presented to us, whose structure and composition we are as yet unacquainted with, but want, if possible, to discover. The manner of proceeding, in this case, is, by taking the whole to pieces, and examining the parts separately, one after another. When, by such a scrutiny, we have thoroughly informed ourselves of the frame and contexture of each, we then compare them together, in order to judge of their mutual action and influence. By this means we gradually trace out the inward make and composition of the whole, and come at length to discern how parts of such a form, and so put together as we found in unravelling and taking them asunder, constitute that particular machine called a *watch*, and contribute to all the several motions and phenomena observable in it. This discovery being made, we can take things the contrary way, and beginning with the parts, so dispose and connect them as their several uses and structures require, until at length we arrive at the whole itself, from the unravelling of which those parts resulted.

123
Illustrated by the simile of a watch.

124
Ground of
the analy-
tic and syn-
thetic me-
thods.

IV. And as it is in tracing and examining the works of art; so is it, in a great measure, in unfolding any part of human knowledge: for the relations and mutual habitudes of things do not always immediately appear upon comparing them one with another. Hence we have recourse to intermediate ideas; and, by means of them, are furnished with those previous propositions that lead to the conclusion we are in quest of. And if it so happen that the previous propositions themselves are not sufficiently evident, we endeavour, by new middle terms, to ascertain their truth; still tracing things backward, in a continual series, until at length we arrive at some syllogism where the premises are first and self-evident principles. This done, we become perfectly satisfied as to the truth of all the conclusions we have passed through, inasmuch as they are now seen to stand upon the firm and immovable foundation of our intuitive perceptions. And as we arrived at this certainty by tracing things backward to the original principles whence they flow; so may we at any time renew it by a direct contrary process, if, beginning with these principles, we carry the train of our thoughts forward until they lead us, by a connected chain of proofs, to the very last conclusion of the series.

125
Division of
method into
analytic and
synthetic.

V. Hence it appears, that, in disposing and putting together our thoughts, either for our own use, that the discoveries we have made may at all times lie open to the review of the mind, or where we mean to communicate and unfold the discoveries to others, there are two ways of proceeding equally within our choice: for we may so propose the truths relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation; carrying on the series of proofs, in a reverse order, until they at last terminate in first principles: or, beginning with these principles, we may take the contrary way, and from them deduce, by a direct train of reasoning, all the several propositions we want to establish. This diversity in the manner of arranging our thoughts gives rise to the twofold division of method established among logicians: for method, according to their use of the word, is nothing else but the order and disposition of our thoughts relating to any subject. When truths are so proposed and put together as they were or might have been discovered, this is called the *analytic method*, or the *method of resolution*; inasmuch as it traces things backward to their source, and resolves knowledge into its first and original principles. When, on the other hand, they are deduced from these principles, and connected according to their mutual dependence, inasmuch that the truths first in order tend always to the demonstration of those that follow; this constitutes what we call the *synthetic method*, or *method of composition*. For here we proceed by gathering together the several scattered parts of knowledge, and combining them into one whole or system, in such manner that the understanding is enabled distinctly to follow truth through all her different stages and gradations.

126
Called o-
therwise
the method
of inven-
tion, and
the method
of science.

VI. There is this farther to be taken notice of, in relation to these two species of method; that the first has also obtained the name of the *method of invention*, because it observes the order in which our thoughts succeed one another in the invention or discovery of truth. The other, again, is often denominated the

method of doctrine or instruction; inasmuch as, in laying our thoughts before others, we generally choose to proceed in the synthetic manner, deducing them from their first principles. For we are to observe, that although there is great pleasure in pursuing truth in the method of investigation, because it places us in the condition of the inventor, and shows the particular train and process of thinking by which he arrived at his discoveries; yet it is not so well accommodated to the purposes of evidence and conviction. For, at our first setting out, we are commonly unable to divine where the analysis will lead us; inasmuch that our researches are for some time little better than a mere groping in the dark. And even after light begins to break in upon us, we are still obliged to many reviews, and a frequent comparison of the several steps of the investigation among themselves. Nay, when we have unravelled the whole, and reached the very foundation on which our discoveries stand, all our certainty, in regard to their truth, will be found in a great measure to arise from that connection we are now able to discern between them and first principles, taken in the order of composition. But in the synthetic manner of disposing our thoughts, the case is quite different: for as we here begin with the intuitive truths, and advance by regular deductions from them, every step of the procedure brings evidence and conviction along with it; so that, in our progress from one part of knowledge to another, we have always a clear perception of the ground on which our assent rests. In communicating therefore our discoveries to others, this method is apparently to be chosen, as it wonderfully improves and enlightens the understanding, and leads to an immediate perception of truth.

VII. The logic which for so many ages kept possession of the schools, and was deemed the most important of the sciences, has long been condemned as a mere art of wrangling, of very little use in the pursuit of truth. Attempts have been made to restore it to credit, but without success; and of late years little or no attention whatever has been paid to the *art of reasoning* in the course of what is called a liberal education. As both extremes may be faulty, it should seem that we cannot conclude this short treatise more properly than with the following

REFLECTIONS on the UTILITY of LOGIC.

IF Aristotle was not the inventor of logic, he was certainly the prince of logicians. The whole theory of syllogisms he claims as his own, and as the fruit of much time and labour; and it is universally known, that the later writers on the art have borrowed their materials almost entirely from his *Organon* and Porphyry's Introduction. But after men had laboured near 2000 years in search of truth by the help of syllogisms, Lord Bacon proposed the method of induction, as a more effectual engine for that purpose; and since his days the art of logic has gradually fallen into disrepute.

To this consequence many causes contributed. The art of syllogism is admirably calculated for wrangling; and by the schoolmen it was employed with too much success, to keep in countenance the absurdities of the Romish church. Under their management it produced numberless disputes, and numberless sects, who

fought against each other with much animosity without gaining or losing ground; but it did nothing considerable for the benefit of human life, whilst the method of induction has improved arts and increased knowledge. It is no wonder, therefore, that the excessive admiration of Aristotle, which continued for so many ages, should end in an undue contempt; and that the high esteem of logic, as the grand engine of science, should at last make way for too unfavourable an opinion, which seems now prevalent, of its being unworthy of a place in a liberal education. Men rarely leave one extreme without running into the contrary: Those who think according to the fashion, will be as prone to go into the present extreme as their grandfathers were to go into the former; and even they who in general think for themselves, when they are offended at the abuse of any thing, are too apt to entertain prejudices against the thing itself. "In practice (says the learned WARBURTON †), logic is more a trick than a science, formed rather to amuse than to instruct. And in some fort we may apply to the art of syllogism what a man of wit says of rhetoric, that it only tells us how to name those tools which nature had before put into our hands. In the service of chicane, indeed, it is a meer juggler's knot, now fast, now loose; and the schools where this legerdemain was exercised in great perfection are full of the stories of its wonders." The authority of Warburton is great; but it may be counterbalanced by another which, on subjects of this nature, is confessedly greater.

"Laying aside prejudice, whether fashionable or unfashionable, let us consider (says Dr REID ‡) whether logic is or may be made subservient to any good purpose. Its professed end is, to teach men to think, to judge, and to reason, with precision and accuracy. No man will say that this is a matter of little importance: the only thing therefore that can admit of doubt is, whether it can be taught?"

"To resolve this doubt, it may be observed, that our rational faculty is the gift of God, given to men in very different measures: Some have a large portion, some a less; and where there is a remarkable defect of the natural power, it cannot be supplied by any culture. But this natural power, even where it is the strongest, may lie dead for want of the means of improvement. Many a savage may have been born with as good faculties as a Newton, a Bacon, or an Aristotle; but their talents were buried by having never been put to use, whilst those of the philosophers were cultivated to the best advantage. It may likewise be observed, that the chief mean of improving our rational power, is the vigorous exercise of it in various ways and on different subjects, by which the habit is acquired of exercising it properly. Without such exercise, and good sense over and above, a man who has studied logic all his life may be only a petulant wrangler, without true judgment or skill of reasoning in any science."

This must have been Locke's meaning, when in his Thoughts on Education he says, "If you would have your son to reason well, let him read Chillingworth." The state of things is much altered since Locke wrote: Logic has been much improved chiefly by his writings; and yet much less stress is laid upon it, and less time consumed in its study. His counsel, therefore, was ju-

dicious and seasonable; to wit, That the improvement of our reasoning power is to be expected much more, from an intimate acquaintance with the authors who reason best, than from studying voluminous systems of school logic. But if he had meant, that the study of logic was of no use, nor deserved any attention, he surely would not have taken the pains to make so considerable an addition to it, by his *Essay on the Human Understanding*, and by his *Thoughts on the Conduct of the Understanding*; nor would he have remitted his pupil to *Chillingworth's*, the acutest logician as well as the best reasoner of his age."

There is no study better fitted to exercise and strengthen the reasoning powers than that of the mathematical sciences; because there is no other branch of science which gives such scope to long and accurate trains of reasoning, or in which there is so little room for authority or prejudice of any kind to give a false bias to the judgment. When a youth of moderate parts begins to study Euclid, every thing is new to him: His apprehension is unsteady; his judgment is feeble; and rests partly upon the evidence of the thing, and partly upon the authority of his teacher. But every time he goes over the definitions, the axioms, the elementary propositions, more light breaks in upon him; and as he advances, the road of demonstration becomes smooth and easy: he can walk in it firmly, and take wider steps, till at last he acquires the habit not only of understanding a demonstration, but of discovering and demonstrating mathematical truths.

It must indeed be confessed, that a man without the rules of logic may acquire a habit of reasoning justly in *mathematics*, and perhaps in any other science. Good sense, good examples, and assiduous exercise, may bring a man to reason justly and acutely in his own profession without rules. But whoever thinks, that from this concession he may infer the inutilty of logic, betrays by this inference a great want of that art; for he might as well infer, because a man may go from Edinburgh to London by the way of Paris, that therefore any other road is useless.

There is perhaps no art which may not be acquired, in a very considerable degree, by example and practice, without reducing it to rules. But practice joined with rules may carry a man forward in his art farther and more quickly than practice without rules.—Every ingenious artist knows the utility of having his art reduced to rules, and thereby made a science. By rules he is enlightened in his practice, and works with more assurance. They enable him sometimes to correct his own errors, and often to detect the errors of others; and he finds them of great use to confirm his judgment, to justify what is right, and to condemn what is wrong. Now mathematics are the noblest *praxis* of logic. Through them we may perceive how the stated forms of syllogism are exemplified in one subject, namely the predicament of quantity; and by marking the force of these forms, as they are there applied, we may be enabled to apply them of ourselves elsewhere. Whoever, therefore, will study mathematics with this view, will become not only by mathematics a more expert logician, and by logic a more rational mathematician, but a wiser philosopher, and an acuter reasoner, in all the possible subjects either of science or deliberation. But when mathematics, instead of being applied to this ex-

† Introduction to Julian, &c.

‡ Appendix to Lord Kames's Sketch on the Principles and Progress of Reason.

cellent purpose, are used not to exemplify logic, but to supply its place; no wonder if logic fall into contempt, and if mathematics, instead of furthering science, become in fact an obstacle. For when men, knowing nothing of that reasoning which is *universal*, come to attach themselves for years to a *single species*, a species wholly involved in *lines and numbers*, the mind becomes incapacitated for reasoning at large, and especially in the search of *moral truth*. The object of mathematics is *demonstration*; and whatever in that science is not demonstration, is nothing, or at least below the sublime inquirer's regard. *Probability*, through its almost infinite degrees, from simple ignorance up to absolute certainty, is the *terra incognita* of the mathematician. And yet here it is that the great *business* of the human mind is carried on in the search and discovery of all the important truths which concern us as reasonable beings. And here too it is that all its *vigour* is exerted: for to proportion the assent to the probability accompanying every varying degree of moral evidence, requires the most enlarged and sovereign exercise of reason.

In reasonings of this kind, will any man pretend that it is of no use to be well acquainted with the various powers of the mind by which we reason? Is it of no use to resolve the various kinds of reasoning into their simple elements; and to discover, as far as we are able, the rules by which these elements are combined in judging and in reasoning? Is it of no use to mark the various fallacies in reasoning, by which even the most ingenious men have been led into error? It must surely betray great want of understanding, to think these things useless or unimportant. Now these are the things which logicians have attempted; and which they have executed—not indeed so completely as to leave no room for improvement, but in such a manner as to give very considerable aid to our reasoning powers. That the principles they have laid down with regard to definition and division, with regard to the conversion and opposition of propositions, and the general rules of reasoning, are not without use, is sufficiently apparent from the blunders committed daily by those who disdain any acquaintance with them.

Although the art of categorical syllogism is confessedly little fitted for the discovery of unknown truth,

it may yet be employed to excellent purposes, as it is perhaps the most compendious method of detecting a fallacy. A man in quest of unknown truths must generally proceed by the way of induction, from effects to causes; but he, who as a teacher is to inculcate any system upon others, begins with one or more self-evident truths, and proceeds in the way of demonstration, to the conclusion which he wishes to establish. Now every demonstration, as has been already observed, may be resolved into a series of syllogisms, of which the conclusion of the preceding always enters into the premises of that which follows: and if the first principles be clear and evident, and every syllogism in some legitimate mode and figure, the conclusion of the whole must infallibly be admitted. But when the demonstration is thus broken into parts; if we find that the conclusion of one syllogism will not, without altering the meaning of the terms, enter legitimately into the premises of that which should immediately follow; or, supposing it to make one of the premises of a *new* syllogism, if we find that the conclusion, resulting from the whole series *thus* obtained, is different from that of the demonstration; we may, in either of these cases, rest assured that the author's reasoning is fallacious, and leads to error; and that if it carried an appearance of conviction before it was thus resolved into its elementary parts, it must have been owing to the inability of the mind to comprehend at *once* a long train of arguments. Whoever wishes to see the syllogistic art employed for this purpose, and to be convinced of the truth of what we have said respecting its utility, may consult the excellent writer recommended by Locke, who, in places innumerable of his incomparable book, has, without pedantry, even in that pedantic age, made the happiest application of the rules of logic for unravelling the sophistry of his Jesuitical antagonist.

Upon the whole, then, though we readily acknowledge that much time was wasted by our forefathers in syllogistic wrangling, and what might with little impropriety be termed the *mechanical* part of logic; yet the art of forming and examining arguments is certainly an attainment not unworthy the ambition of that being whose highest honour is to be endued with reason.

Logiste,
Logograp-
hy.

LOGISTÆ, certain officers at Athens, in number ten, whose business consisted in receiving and passing the accounts of magistrates when they went out of office. The *logistæ* were elected by lot, and had ten *euthyni* or auditors of accounts under them.

LOGOGRAPHY, a new method of printing, in which the types, instead of answering only to single letters, are made to correspond to whole words.

This method, though seemingly a retrograde procession in the printing art, has lately obtained the sanction of his Majesty's patent, and has for some time been actually put in execution in the way of trade, apparently with advantage to the proprietors. In the year 1783, a treatise upon this subject appeared, by Henry Johnson, in which the origin as well as

the utility of the art are fully laid down, and the matter set forth in such a light as can scarce allow us to doubt that it is an improvement in the art. Mr Johnson informs us, that about five years before, viz. in the year 1778, intending to publish a daily list of blanks and prizes in the lottery numerically arranged, he found it could not be accomplished in time by the ordinary way of printing. On this account he procured types of two, three, or more figures as was necessary for his purpose; and thus any entire number might as readily be taken up as if it had been a single type. His next attempt was in forming some large mercantile tables of pounds, shillings, pence, and farthings. For these he procured types expressive of any sum of money ready composed and united, "by
which.

Logograp-
hy.

Logog-
raphy.

which (says he) every species of figure-printing could be performed for the tenth part of the cost, printers always charging it double the price of letter printing." Having thus succeeded to his wish in his two first attempts, he next began to consider if the method could not be applied to words; and in this also the success was equal.

The properties of the logographic art, according to our author, are, 1. That the compositor shall have less charged upon his memory than in the common way. 2. It is much less liable to error. 3. The type of each word is as easily laid hold of as that of a single letter. 4. The decomposition is much more readily performed, even by the merest novices, than they now decompose letters. 5. No extraordinary expence nor greater number of types is required in the logographic than in the common method of printing.

The first of these positions is proved by our author in the following manner. In the common method, the compositor has 150 divisions to which there is no reference, and the printing offices are not agreed with respect to the mode of placing their boxes; "but under this improvement, he has only to know the letters of the alphabet, and is assisted with an index of them, inasmuch that the simplicity of the latter apparatus enables him, by a little practice, to lay his finger almost blindfold on the word required; and the meanest capacity is equal to this mental exercise, having little more to do than knowing by inspection the difference between words under three and those above three syllables; and all the apparatus being within a compass not a great deal more extended than common printing, for these reasons he is as soon possessed of his type of a word as they are of a single letter."

Thus the first and third positions may be said to be proved; but in his proof of the second, our author himself shows that his art is not infallible, by substituting the word *third* instead of *second*. Substitutions of this kind, he owns, may readily take place; but such errors are much more conspicuous than literal ones, though they may be corrected with equal ease; "for the erroneous substitution cannot fail of being nearly equal in length to the word required; although, even otherwise, it would not be attended with greater disadvantage than in the common way, and it would be rectified with greater facility."

The ease with which the composition is performed, shows that there must be an equal ease in performing the decomposition; "from whence (says Mr Johnson)" it is further demonstrable, that any work can be composed by this method nearly as soon as it can be deliberately read; and as to the fifth position, that it shall not require a greater expence of types, it is answered, that it is impossible for more types of letters to be wanted for this method than by any other printer according to the equal quantity of business to be performed, every office having certain known quantities of each letter called a *fount*. A printer's fount contains about 92,500 letters, and our want is not more; nay, nearer the truth, the present quantity for a fount containing much more of some letters than necessary, and fewer of others; which arises from the calculation of the quantity of each letter wanted being adhered to since the old spelling.

Logog-
raphy.

Our author now proceeds to demonstrate that the number of types must necessarily decrease as they are combined into syllables, and much more when formed into words. The whole art of arranging the words consists in placing them under as few divisions as possible, and fill fewer subdivisions; which is attained by the following process.

1. A collection of words, with the addition of tenses, plurals, and degrees of comparison, amounting to more than 100,000, was made from the best English dictionaries.

2. Collections were made from the miscellaneous part of 20 newspapers, the *Spectator*, and Common Prayer-book. The method was, by procuring duplicates of every sheet, so that each alternate side might be pasted over with white paper, in order to leave the whole of the words on both sides perfect; and thus the whole might be touched with less danger of injury than otherwise could have been done. The confusion arising from the parts of other words being seen from the opposite side was likewise prevented.

3. The words, being separately cut out, were then put into a case marked with the divisions from one to 16, according to the number of letters contained in each word. Thus several letters were distinctly collected; and then each separate parcel sorted in a case containing 26 divisions, marked with the letters of the alphabet, according to the commencing letter of the word; and thus all the words were ranged alphabetically, consisting of two, three, four, or five letters, in separate parcels.

4. The same words were then placed together, and poised into an alphabet, with the number of times marked to each that had occurred on the whole; that in this manner a proportion might be determined how many times particular words ought to be repeated for the printing of one sheet, and also to know what words are in general use: There are likewise a number of technical terms, and favourite phrases a great number of times repeated almost by every author, but though these occur throughout the whole book in great proportion to the rest, no more of them will be necessary than what suffice for a single sheet.

5. The whole of the above might be done without the trouble just mentioned, by poising every word at once into a transformed alphabet; because the subdivisions of the second and third commencing letter of each word for references are now obtained, and thus can easily be placed in its proper division, and may be marked as often as it occurs, without repeating the same word; whence we plainly see the ease and expedition of it, from the facility and expedition of poising every word from a leaf in any book. Before such subdivisions were known, they could only have been placed under the first commencing letter of the word; which would cause such a multiplicity of repetitions, that it would take up more time, be far more liable to error, and require more subordinate poissings to bring them into arrangement; so that they may be found more easily than by the above proceedings. Thus also a collection will be obtained of single and double words, which are constantly required from 20 to 400 or 500 times in the printing one sheet of any work whatever; and which alone would abridge the compositor's work near one-third. This second process

likewise

Logog-
phy.

Logog-
phy.

likewise enabled the author to reject, out of the first collection, obsolete words, technical terms, &c. which reduces the original collection to one fifth part.

6. By proceeding in this manner, several species of words are omitted in the founts. 1. Obsolete words; because they occur so seldom, that the difference of time lost in composing them in the ordinary method would be imperceptible. 2. Technical terms, names of places, animals, &c.; though, for any particular work, the terms peculiar to it may be added to the fount in a bifurmed alphabet apart. 3. Real compounds, or words that may be compounded of others, are also rejected; because we actually have the words already, and they may be joined with sufficient expedition, though the spaces are annexed to each, by being constructed accordingly. 4. Those of the same spelling are likewise omitted, though they bear different significations, for obvious reasons.

7. The variation of tenses, degrees of comparison, and numerous words in the English language, having in general the same terminations, such as ED, ING, LY, MENT, NESS, &c. an alphabet may be formed of such a kind as is capable of being annexed to the absolute words or radices, as expeditiously as the whole word could be found in the fount, from its being thereby so much less extended. Thus, by dividing several words into their radices and terminations, many other words may be formed from the radix by the addition of various terminations, and each termination may be added to other radices to which they are applicable.

8. Some radices are imperfect, viz. such as end with the vowel *e*, which must therefore be added in the usual way of composition. Thus, in the word *adore*, the radix is *ador*, to which the terminations *es*, *ed*, *eth*, *er*, *ing*, may be added occasionally.

9. By rejecting also the words which come under this last denomination, the number necessary for a fount is reduced to one-tenth of what it would otherwise be, as will appear evident from the following considerations: 1. There are at least 42 verbs, the infinitive of which ends in *ify*; as *qualify*, *signify*; the radices of which are *qual*, *sign*; the terminations are, *ifies*, *ified*, *ifying*, &c. And Mr Johnson informs us, that by applying these radices to other terminations, he was enabled to dispense with more than 500 words which would otherwise have been necessary. 2. For all regular verbs, no more than six terminations are necessary, viz. *t*, *eth*, *ed*, *es*, *ing*. There are but few irregular ones in the English language; whence it happens that 12 or 14 words may be formed from one single perfect verb as a radix, and many imperfect ones have double that number.

10. By using only the set of terminations which may be contained in a box of two feet square, the common operation of printing would be shortened nearly one half; and in order to find out those which are most in use, and fittest to retain, our author digested them alphabetically, with the radices, words, or syllables, which make complete words annexed to them. Thus,

tain	}	abs—apper—after
—s		de—dis—con
—ed		cer—cap—cur
—ing		enter—main—re—fus, &c.
—ment		

11. Thus it will be found, that out of more than 100,000 words of which the English language consists, there will not be wanted much above 3,000 for a complete fount. This will be very evident to any person who consults a dictionary. He will there find, that a vast number of words require an explanation; whereas in any miscellaneous work, there are none but what can be understood most readily either together or apart. Newspapers retain more of the uncommon kind of words than any others. "The vocabulary (says our author) or alphabet as it is called, of the Chinese, consists of above 80,000 letters or characters; yet he is admitted a master of the language who knows about 4000 of them, no more being in general use."

The expedition with which the logographic method of printing can be accomplished, depends essentially on their arrangement; which, from great numbers of experiments, our author found to be best accomplished in the following manner: 1. Words of one, two, or three syllables, are alphabetically placed by themselves, including all possible commencing syllables, by which the compositor cannot fail of finding the word either in whole or in part let it be what it will; and when the whole cannot be found at once, the remainder may easily be found in single or double syllables among the terminations. 2. All words above three syllables have the same alphabetical arrangement; the terminations being the same at the bottom of each. Experience shows, that by a very few lessons, the meanest capacity may determine the number of syllables, and refer to the particular case containing words of that number, there being conspicuous references to each; and by thus equalizing them, any person may possess himself very expeditiously of what he wants. Even boys who scarce knew more than the letters of the alphabet, were hardly a fortnight employed in this method, when they could at the first glance tell the number of letters contained in any word.

By this simplicity of arrangement, any intelligent person, who never composed in his life, by being placed in a room with the apparatus, could compose and print, without other previous instruction than desiring him to remember that the words under three syllables, and those above three, are placed in separate alphabets; and that whenever he wants a word, the first letter is seen in capitals of two inches on the walls, the second in letters of one inch in right lines; and where it is necessary to have more columns than one for such second letter, the third is given in red down the column, comprehending about 12 divisions, to contain the types of the word coming under such reference.

To exemplify this method as far as it can be done without actually seeing the apparatus, our author instances the two words *above* and *Unfortunately*. In looking for the former, the first letter, A, is seen upon the wall as already mentioned; the second, B, is on the case under it, and down that column is OVE, opposite to the cell containing the types of the whole word; which would be only three references instead of five with spaces, as in the common method. The other word, viz. *Unfortunately*, may be found by the same references, though it contains 13 letters; but "admitting that practice will give the word as soon as a single letter, the average will be found eight for one."—Our author's explanation of the method in which this word might be composed, however, seems by

Logogra-
phy.

by no means intelligible.—“For this distinction in the cafes (says he), the alphabet, or rather marks of first reference in large characters on the wall, is divided into two classes, not as vowels and consonants, but as follows, *viz.* A, Con, Dis, E, In, O, P, S, Un, commencing references, the second or subsequent letters of the words being in a right line from left to right, and down each column is found the remainder of the reference to the words, distinguishing always the third letter in red. The second distinction is, that for all other commencing letters, the second letter of reference is in a column down, and the third letter in lines from left to right in red.

These are the directions given by our author for forming a fount of words; the next requisite is a fount of syllables, formed in the following method: 1. A complete set of two letters was obtained in all their possible combinations, amounting to 676. 2. Having next obtained the possible combination of these letters, *viz.* 17,576, by retaining only all possible syllables, and words of three letters, it is reduced to the 30th part, which answer all the purposes of composing with syllables of two and three letters, for Latin, French, English, and all names of persons, places, and things, every possible syllable being comprehended among them. Hence it forms an universal triformed alphabet, where English characters are used; from whence all partial bi-formed and tri-formed alphabets in the arrangement of English, French, Latin, and all technical matters, are drawn. Though combinations of four letters are again 26 times the number of those of three letters, and five letters increase in the same ratio; yet as much as all possible combinations increase in quantity proportionate to the number of letters combined, so they decrease in the actual number of syllables included among them, inasmuch, that all the syllables of four, five, six, and seven letters together, are considerably more than the syllables of three letters only.—Besides the two founts already mentioned, a third was found necessary for such terminations as are most commonly followed by particular punctuations; but, after some consideration, this was judged unnecessary.

Our author now proceeds to obviate some objections which must naturally occur to one who first hears of his invention. These are,

1. A single letter damaged in a word renders the whole useless.

This is not denied by Mr Johnson; but he contends, that the quantity of metal lost in this manner is quite trifling.

2. How are the blanks or spaces in a line to be managed, as these are by no means equal?

To this our author replies, that, at the time of writing the pamphlet, he was undetermined whether it be most eligible to have spaces cast along with the beginnings of words, or to space them in the common manner. The former would be more expeditious; and where a greater distance is required, other spaces may be introduced in the ordinary method.

3. How is a long word at the end of a line to be divided?

This may be easily accomplished by means of the syllabic fount already mentioned.

4. How is the error of substituting one word for another to be rectified?

Nº 186.

The answer to this is, that an error of the kind specified may be corrected in the very same manner as is done in common printing. Long words may be divided by means of the syllabic fount already mentioned, and the intervals between the words may be filled up with spaces as usual.

LOGWOOD. See HÆMATOXYLON.

LOHOCH, or LOCH, in pharmacy, a composition of a middle consistence between a soft electuary and a syrup, principally used in disorders of the lungs.

LOINS, in anatomy, the two lateral parts of the umbilical region of the abdomen.

LOIRE, the largest river in France, rises in the mountains of the Cevennes, and, after running a course of about 500 miles, falls into the bay of Biscay.

LOKE, in mythology, the name of one of the deities of the northern nations, answering to the Arimanes among the Persians, whom they represent as at enmity both with gods and men, and the author of all the evils which desolate the universe. Loke is described in the Edda as producing the great serpent which incircles the world; which seems to have been intended as an emblem of corruption or sin: he also gives birth to Hela or death, the queen of the infernal regions; and also to the wolf Fenris, that monster who is to encounter the gods and destroy the world.

LOKMAN the WISE, an eminent philosopher among the Easterns. The Arabians say he was the son of Baura, the son or grandson of a sister or aunt of Job. He was an Ethiopian, and a slave for some time. It is related that he was born in the time of David, and lived till the age of the prophet Jonas. Some suppose him to have been the same with Æsop the mythologist; and indeed we find in the parables or apologies of Lokman in Arabic, many particulars that are seen in Æsop's fables; so that it is not easy to determine whether the Greek or the Arabian are the originals. He is said to have been deformed in his person; but that this defect was sufficiently made up by the perfections of his mind. Some pieces of his are extant; and he was looked upon as so excellent a person, that Mahomet has inserted a chapter of the Koran, called after his name, in which he introduces God as saying, “We heretofore bestowed wisdom on Lokman.”—It is related that he got his liberty on the following occasion. His master having given him a bitter melon to eat, he eat it all. His master, surprised at his exact obedience, asked, How it was possible for him to eat such a nauseous fruit? He answered, “I have received so many favours from you, that it is no wonder I should once in my life eat a bitter melon from your hand.” This generous answer of the slave struck the master to such a degree, that he immediately gave him his liberty. M. Galland translated all the fables of Lokman, and Bidpai or Pilpay a bramin philosopher, which were published at Paris in 1724.

LOLIUM, DARNELL-GRASS, in botany: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx is monophyllous, fixed, and unisporous. The most remarkable species are, 1. The perenne, red darnel, or rye-grass. This is very common in roads and dry pastures. It makes excellent hay upon dry, chalky, or sandy soils. It is advantageously cultivated along with clover, and
springs

Logogra-
phy.

Lolium.

Lollards. springs earlier than other grasses; thereby supplying food for cattle at a time when it is most difficult to be obtained. Cows, horses, and sheep eat it; goats are not fond of it. 2. The temulentum, or white dandel, grows spontaneously in ploughed fields. If the seeds of this species are malted with barley, the ale soon occasions drunkenness; mixed with bread-corn, they produce but little effect unless the bread is eaten hot.

LOLLARDS, in ecclesiastical history, a religious sect, differing in many religious points from the church of Rome, which arose in Germany about the beginning of the 14th century; so called, as many writers have imagined, from Walter Lollard, who began to dogmatise in 1315, and was burnt at Cologne: though others think that Lollard was no surname, but merely a term of reproach applied to all heretics who concealed the poison of error under the appearance of piety.

The monk of Canterbury derives the origin of the word Lollard among us, from *lollum*, "a tare;" as if the Lollards were the tares sown in Christ's vineyard. Abelly says, that the word Lollard signifies "praising God," from the German *loben*, "to praise," and *herr*, "Lord;" because the Lollards employed themselves in travelling about from place to place, singing psalms and hymns.

Others, much to the same purpose, derive *lollbard*, *lollbard*, or *lollert*, *lullert*, as it was written by the ancient Germans, from the old German word *lullen*, *lollen*, or *lallen*, and the termination *bard*, with which many of the High Dutch words end. *Lollen* signifies "to sing with a low voice;" and therefore Lollard is a singer, or one who frequently sings; and in the vulgar tongue of the Germans it denotes a person who is continually praising God with a song, or singing hymns to his honour. The Alexians or Cellites were called *Lollards*, because they were public singers who made it their business to enter the bodies of those who died of the plague, and sang a dirge over them in a mournful and indistinct tone as they carried them to the grave. The name was afterwards assumed by persons that dishonoured it; for we find, among those Lollards who made extraordinary pretences to piety and religion, and spent the greatest part of their time in meditation, prayer, and such acts of piety, there were many abominable hypocrites, who entertained the most ridiculous opinions and concealed the most enormous vices under the specious mark of this extraordinary profession. And many injurious aspersions were propagated against those who assumed this name by the priests and monks; so that, by degrees, any person who covered heresies or crimes under the appearance of piety, was called a *Lollard*. Thus the name was not used to denote any one particular sect, but was formerly common to all persons and all sects who were supposed to be guilty of impiety towards God or the church, under an external profession of extraordinary piety. However, many societies, consisting both of men and women under the name of *Lollards*, were formed in most parts of Germany and Flanders, and were supported partly by their manual labours, and partly by the charitable donations of pious persons. The magistrates and inhabitants of the towns where these brethren and sisters resided, gave them

particular marks of favour and protection, on account of their great usefulness to the sick and needy. They were thus supported against their malignant rivals, and obtained many papal constitutions by which their institute was confirmed, their persons exempted from the cognisance of the inquisitors, and subjected entirely to the jurisdiction of the bishops; but as these measures were insufficient to secure them from molestation, Charles duke of Burgundy, in the year 1472, obtained a solemn bull from Pope Sixtus IV. ordering that the Cellites or Lollards should be ranked among the religious orders, and delivered from the jurisdiction of the bishops; and Pope Julius II. granted them yet greater privileges in the year 1506. Mosheim informs us that many societies of this kind are still subsisting at Cologne, and in the cities of Flanders, though they have evidently departed from their ancient rules.

Lollard and his followers rejected the sacrifice of the mass, extreme unction, and penances for sin; arguing, that Christ's sufferings were sufficient. He is likewise said to have set aside baptism, as a thing of no effect; and repentance, as not absolutely necessary, &c.—In England, the followers of Wickliffe were called, by way of reproach, *Lollards*, from some affinity there was between some of their tenets; though others are of opinion, that the English Lollards came from Germany.

They were solemnly condemned by the archbishop of Canterbury and the council of Oxford.

LOMBARD (Lambert), an eminent painter, born at Liege in 1500; who, after a diligent study of the antique at Rome, introduced that style of painting among his countrymen instead of the Gothic. He painted history, architecture, and perspective; and though he could never altogether free himself from his national goit, he is ranked among the best painters of his time. He died in 1560.

LOMBARD (Peter), well known by the title of *Myfter of the Sentences*, was born at Novara in Lombardy; but being bred at Paris, he distinguished himself so much at that university, that he first had the canonry of Chartres conferred on him, was some time tutor to Philip son of Louis le Gros, and lastly obtained the see of Paris. He died in 1064. His work of the *Sentences* is looked on as the source of the scholastic theology of the Latin church. He wrote also Commentaries on the Psalms, and on St Paul's Epistles.

LOMBARDS, a Scandinavian nation, who formerly settled in Italy, and for some time made a considerable figure.

Their name of *Lombards*, or *Longobards*, is by some derived from the word *lack*, or *lache*, signifying in the German tongue *winter*; because the Lombards, while in Scandinavia, lived in marshes, or near the sea. Others think that it comes from the two German words *langen barden*, or *bellidorden*, that is, from the long halberds they were supposed to use in war. But Paulus Diaconus their historian, and who was himself a Lombard, tells us, that they were called *Longobards* from the length of their beards. A nation called the *Lombards* is mentioned by Tacitus, Strabo, and Ptolemy; but these are different from the Lombards who afterwards settled in Italy, and are reckoned to be the same with

name.

Lombards the Gepidæ, whom the Italian Lombards almost exterminated. The Lombards who settled in Italy are first mentioned by Prosper Aquitanus, bishop of Rhegium in the year 379. That writer tells us, that about this time the Lombards, abandoning the most distant coasts of the ocean, and their native country Scandinavia, and seeking for new settlements, as they were overstocked with people at home, first attacked and overcame about this time the Vandals in Germany. They were then headed by two chiefs, Iboreus and Aion; who, dying about the year 389, were succeeded by Agilmund, who is commonly reckoned the first king of the Lombards.

3 Before the time of Odoacer, the Lombard history affords nothing remarkable; in his time, however, they settled on the Danube, in the country of the Rugians, whom Odoacer had almost totally exterminated or carried into captivity. During their stay in this country, they rendered themselves formidable to the neighbouring nations, and carried on successful wars with the Heruli and Gepidæ. In 526, they were allowed by the emperor Justinian to settle in Pannonia; and here they made war a second time with the Gepidæ. Alboinus, the Lombard king, killed the king of the Gepidæ with his own hand, put his army to the rout, and cut such numbers of them in pieces, that they ceased from that time to be a nation.

4 Having caused the deceased king's head to be cut off, he made a cup of his skull, called in the language of the Lombards *fibula*, which he made use of in all public entertainments. However, having taken, among many other captives of great distinction, the late king's daughter, by name *Rosamunda*, he married her after the death of his former wife Clodivinta, the daughter of Clotaire king of France.

By this victory Alboinus gained such reputation, that his friendship was courted by Justinian; and, in consequence of the emperor's application, a body of 6000 Lombards were sent to the assistance of Narfes against the Goths. The success of the Romans in this expedition, the invasion of Italy by the Lombards, and their successes in that country, have been taken notice of under the article ITALY, n° 28—32. At last Alboinus, having made himself master of Venetia, Liguria, Emilia, Hetruria, and Umbria, was slain by the treachery of his wife, in the year 575, the fourth of his reign. This princess was the daughter of the king of the Gepidæ, whom Alboinus had killed in battle, and made a cup of his skull, as above related.

5 As he was one day feasting at Verona with his chief favourites and principal officers, in the height of his mirth he sent for the queen, and, filling the detested cup, commanded her to drink merrily with her father. Rosamund, struck with horror, hurried out of the room; and highly incensed against her husband for thus barbarously triumphing over the misfortunes of her family, resolved, at all events, to make him pay dear for such an inhuman and affronting conduct. Accordingly, she discovered her intention to Helmichild the king's shield-bearer, a youth of great boldness and intrepidity. Helmichild pre-emptorily refused to imbrue his hands in the blood of his sovereign, or to be any way accessory to his death; and in this resolution he persisted till he was, by a shameful stratagem, forced by the queen to a compliance: for she,

knowing that he carried on an intrigue with one of her ladies, placed herself one night in her bed, and receiving the youth, indulged him as if he had been his own mistress in his amorous desires; which he had no sooner done, than, discovering herself to the deceived lover, she told him that he must now either put the king to death, or be put to death by him. Helmichild, well apprised, that, after what he had done, his safety depended upon the death of the king, engaged in the treason, which he otherwise abhorred. One day, therefore, while Alboinus was repining in his chamber after dinner, Helmichild, with some others whom he had made privy to his design, breaking in unexpectedly, fell upon the king with their daggers. Alboinus, starting up at their first coming in, laid hold of his sword, which he had always by him; but having in vain attempted to draw it, the queen having beforehand fastened it in the scabbard, he defended himself for some time with a footstool; but was in the end overpowered, and dispatched with many wounds.

Rosamund had promised to Helmichild, that, as soon as he had dispatched the king, she would marry him, and, with her person, bestow upon him the kingdom of the Lombards. The first part of her promise she immediately performed; but was so far from being able to bestow the crown upon him, that both of them were obliged to save themselves by flight. They fled to Longinus the exarch of Ravenna, taking with them all the jewels and treasure of the late king. Longinus received her with the greatest marks of friendship and kindness, and assured her of his protection. She had not been long in Ravenna, however, before the exarch, judging that a favourable opportunity now offered of making himself king of Italy by her means, imparted his design to her, and declared his intention to marry her, provided, by some means or other, she dispatched Helmichild.—Rosamund, highly pleased with the proposal, resolved to satisfy her ambition by getting rid of the person whom she had married in order to gratify her revenge. Accordingly, having prepared a strong poison, she mixed it with wine, and gave it to her husband as he came out of the bath, and called for drink, according to his custom. Helmichild had not half emptied the cup, when, by the sudden and strange operation which he felt in his bowels, he concluded what it was; and, with his sword pointed at the queen's breast, compelled her to drink the rest. The poison had the same effect on both; for they died in a few hours. Longinus, on the death of the queen, laid aside all thoughts of making himself king of Italy, and sent the king's treasure to Constantinople, together with Alboinda, the daughter of Alboinus by Rosamund, whom he had brought along with her.

After the death of Alboinus, the Lombards chose Clephis, one of the nobility, for their king. He was murdered after a short reign of 18 months; upon which ensued an interregnum of 10 years, as related under the article ITALY, n° 32. During this time, they extended their conquests in that country; but at last the Romans, jealous of their progress, resolved to put a stop to their victories, and, if possible, to drive them quite out. For this purpose, they designed not only to employ their own force, but entered into alliance with the Franks; which so alarmed the Lombards, that they re-established the monarchical form of government.

Alboinus king of the Lombards assassinated at the instigation of his wife.

6 Her death.

7 Monarchy abolished.

Lombards, vernment among themselves, and chose Autharis the son of Clephis for their king. This monarch, considering that the power of the dukes, who had governed Lombardy for the space of 10 years, was during that length of time very much established, and that they would not probably be willing to part with the authority which they had so long enjoyed, allowed them to continue in their government; but obliged them to contribute one moiety of their revenues towards the maintenance and support of his royal dignity, suffering them to dispose of the other as they thought proper. He reserved to himself the supreme dominion and authority; and took an oath of the dukes, that, in time of war, they would readily assist him to the utmost of their power. Though he could remove the dukes at pleasure, yet he deprived none of them of their dukedoms, except in cases of treason; nor gave them to others, except when their male issue failed. Having settled matters in this manner with the dukes, he enacted several wholesome laws against theft, rapine, murder, adultery, and other vices which prevailed among his subjects, and was the first of the Lombard kings who embraced Christianity. Most of his subjects followed the example of their monarch: but as they were all instructed by Arian bishops, they continued long infected with that heresy; which occasioned great disputes between them and the orthodox bishops of the cities subject to them.

From the re-establishment of the monarchy under Autharis, to the reign of Rotharis in 636, the history of the Lombards affords nothing memorable. This period is remarkable for the introduction of written laws among these people. Before his time they had been governed only by tradition; but Rotharis, in imitation of the Romans and Goths, undertook the publishing of written laws; and to those which he enacted, many were added by the succeeding princes. Grotius prefers the method which the Lombards followed in making laws, to that which was practised by the Romans themselves. Among the latter the emperor was the sole lawgiver; so that whatever pleased him had the force of a law. But the Lombard kings did not assume that power to themselves, since their laws were enacted in public assemblies, convened for that purpose, after they had been maturely examined and approved of by all the lords of the kingdom. From these assemblies were excluded the ecclesiastic order, and the people; so that the legislative power was lodged in the king and nobles alone.

The reign of Rotharis is remarkable, not only for his introducing written laws among his subjects, but for the conquests he made, and the successful wars carried on with the exarch of Ravenna, whom he totally defeated in several engagements, and made himself master of some part of his territories. This monarch died in 652; and the affairs of the Lombards went on prosperously, till the ambition of Luitprand laid the foundation of the total ruin of his kingdom. He ascended the throne of Lombardy in 711, and watched all opportunities of enlarging his dominions at the expence of the emperors. Of this, a fair opportunity offered in 716: for the emperor Leo Isauricus, who at that time reigned in the east, having, by his famous edict, forbidden the worship of images, and ordered them to be every where pulled down, the

people were so provoked at that innovation, that, in several places, they openly revolted, and, falling upon the emperor's officers, drove them out of the cities. In the east, Germannus, patriarch of Constantinople, opposed the emperor's design with great warmth; but Leo caused him to be deposed, and Anastasius to be raised to that see in his room, ordering at the same time all the images in the imperial city to be pulled down and publicly burnt. He strictly enjoined his officers in the west, especially the exarch of Ravenna, to see his edict punctually obeyed in their respective governments. In compliance with these orders, Scholasticus, then exarch, began to pull down the images in all the churches and public places in Ravenna; which incensed the superstitious multitude to such a degree, that, taking arms, they openly declared they would rather renounce their allegiance to the emperor than the worship of images.

Thus a kind of civil war being kindled in the city, Luitprand thought he had now a favourable opportunity of making himself master of the seat of the exarch, not doubting but the conquest of such an important place would be followed by that of the whole exarchate. Having therefore drawn together all his forces, he unexpectedly appeared before Ravenna, and closely besieged it. The exarch little expected such a surprise, as a friendly correspondence had been maintained for many years between the exarchs and the Lombard kings. However, he defended the place with such courage and resolution, that Luitprand, despairing of success, broke up the siege and led his army against Clasis, at a small distance from Ravenna, which he took, plundered, and levelled with the ground. The loss of this place, and the severe treatment the inhabitants met with from the king, threw the citizens of Ravenna into the utmost consternation; which Luitprand being informed of, he resolved to take advantage of their fears, and, returning before Ravenna while the inhabitants were thus disheartened, to attempt once more the reduction of that place. Accordingly he led his whole army against it, and, by frequent attacks, tired the inhabitants and garrison to such a degree, that the exarch, finding they could hold out no longer, and despairing of relief, privately withdrew. Luitprand, informed of his retreat, attacked the town with more violence than ever; and, having carried it by storm, gave it up to be plundered by his soldiers, who found in it an immense booty, as it had been for a long time the seat of the Roman emperors, of the Gothic kings, and the exarchs. The king stripped it of most of its valuable monuments of antiquity, and caused, among the rest, an equestrian statue of an emperor, of wonderful workmanship, to be conveyed to Pavia, where it is to be seen to this day. The reduction of Ravenna was followed by the surrender of several cities of the exarchate, which Luitprand reduced to a dukedom; appointing Hildebrand his grandson to govern it with the title of duke; and giving him, as he was yet an infant, Perekus deus duke of Vicenza for his guardian.

The conquest of Ravenna and the greater part of the exarchate did not a little alarm Gregory II. bishop of Rome. He was then at variance with the emperor, whose edict against the worshipping of images he had opposed with all his might, and by that

Lombards means provoked Leo to such a degree, that he had threatened to drive him from the see, and send him into exile. However, the pope, no less jealous of the power of the Lombards than all his predecessors had been, resolved, by some means or other, to put a stop to their conquests. The only prince in Italy to whom he could have recourse was Ursus duke of Venice, the Venetians making already no inconsiderable figure. To him accordingly he wrote a very pressing letter; conjuring him to assist his worthy son the exarch, and for the love of the holy faith, to attempt with him the recovery of the exarchate, which the wicked nation of the Lombards had unjustly taken from his sons Leo and Constantine emperors. Ursus and the Venetians, moved with the pope's letter, and at the same time greatly alarmed at the growth of so powerful a neighbour, promised to assist the exarch with the whole strength of their republic; and accordingly fitted out a considerable fleet, pretending it was designed for the service of the emperor against the Saracens. At the same time the exarch, who had taken refuge in Venice, abandoning that place, as it were in despair of bringing the duke over to his party, raised, in the places still subject to the emperor, what forces he was able; and having got together a considerable body, he marched with them towards Imola, giving out that he designed to besiege that city; but, turning on a sudden towards Ravenna, as had been agreed on between him and the Venetians, he laid siege to it by land, while they invested it almost at the same instant by sea. Peredeus defended the town for some time with great courage and resolution; obliging all those who were able to bear arms to repair to the walls. But the Venetians having, in spite of all opposition, forced open one of the gates on the side of the sea, the city was taken, and Peredeus slain, while he was attempting, at the head of a choice body, to drive the enemy from the posts they had seized. As for Hildebrand, he fell into the hands of the Venetians; who, having thus recovered Ravenna to the emperor, returned home, leaving the exarch in possession of the city. Luitprand was then at Pavia; but the town was taken before he could assemble his troops to relieve it.

14
Who retake
Ravenna.

And now Gregory bishop of Rome, to whom the recovery of Ravenna was chiefly owing, persuading himself, that the emperor would, out of gratitude, give ear to his remonstrances and admonitions, began to solicit him with more pressing letters than ever to revoke his edict against the worship of images: but Leo, well apprised that the bishop, in all the measures he had taken, had been more influenced by a regard to his own interest, than to that of the empire, instead of hearkening to his remonstrances, was still more provoked against him for thus obstinately opposing the execution of his edict. Being, therefore, resolved at all events to have it observed in Rome itself, and, on the other hand, not doubting but the pope would oppose it to the last with all his might; in order to remove all obstacles, he sent three officers to Rome, with private orders, either to dispatch the pope, or to take him prisoner and convey him to Constantinople. At the same time, he wrote to Mauritius duke of Rome, secretly enjoining him to assist his three officers in their undertaking: but no favourable opportunity offering to put their design in execution, the emperor,

in the year 725, recalled Scholasticus, and sent Paul a patrician into Italy, to govern in his room, with private instructions to encourage the above-mentioned officers with the promise of great rewards, and to assure them of his protection.

But, in the mean time, the plot was discovered, and two of the conspirators were apprehended by the citizens of Rome, and put to death; the third having escaped into a monastery, where he took the monastic habit, and ended his days. Hereupon the exarch, in compliance with the emperor's orders, resolved to proceed no longer by secret plots, but by open force. Accordingly, he drew together a considerable body of troops, and set out at the head of them on his march to Rome, with a design to seize on the pope, and send him, as he had engaged to do, in chains to Constantinople. But, on this occasion, Luitprand, though highly provoked against Gregory for having stirred up the Venetians against him, yet resolved to assist him and the citizens of Rome against the exarch, in order to keep the balance even between them, and by assisting sometimes the one and sometimes the other, weaken both. Pursuant to this resolution, he ordered the Lombards of Tuscan, and those of the dukedom of Spoleto, to join the pope and the inhabitants of Rome; who, being by this reinforcement far superior in strength and number to the exarch, obliged him to return to Ravenna, and give over all thoughts of any further attempt on the person of the pope.

15

pope against
the exarch.

In the mean time, Leo, persisting in his former resolution of suppressing throughout his dominions the worship of images, sent fresh orders to the exarch Paul, strictly enjoining him to cause his edict to be put in execution in all the cities of Italy under his empire, especially in Rome. At the same time, he wrote to the pope, promising him his favour and protection if he complied with the edict; and declaring him, if he continued to oppose it, a rebel, and no longer vested with the papal dignity. But Gregory was so far from yielding to the emperor's threats or promises, that, on the contrary, he solemnly excommunicated the exarch for attempting to put the imperial edict in execution; and at the same time wrote circular letters to the Venetians, to king Luitprand, to the Lombard dukes, and to all the chief cities of the empire, exhorting them to continue steadfast in the Catholic faith, and to oppose with all their might such a detestable innovation. These letters made such an impression on the minds of the people in Italy, that, though of different interests, and often at war with one another, they all united; protesting they would defend the Catholic faith, and the life of the pope, in so glorious a cause, at the expense of their own: nay, the citizens of Rome, and the inhabitants of Pentapolis, now Marca d'Ancona, not contenting themselves with such a protestation, openly revolted from the emperor; and, pulling down his statues, they elected, by their own authority, magistrates to govern them during the interregnum. We are even told, that, transported with a blind zeal, they were for choosing a new emperor, and conducting him to Constantinople, not doubting but the people would every-where join them. But the pope, thinking this resolution unseasonable, and not to be easily put in execution, opposed it; so that it did not take place.

Lombards.

16
A civil war
in Ravenna

In the mean time, the exarch Paul, having gained a considerable party in Ravenna, began, pursuant to the repeated orders from the emperor, to remove the images, as so many idols, out of the churches. Hereupon the adverse party, supported and encouraged by the pope, flew to arms; and, falling upon the *iconoclasts* or image-breakers, as they styled them, gave rise to a civil war within the walls of Ravenna. Great numbers were killed on both sides: but those who were for the worship of images prevailing in the end, a dreadful slaughter was made of the opposite party; and, among the rest, the exarch himself was murdered. However, the city of Ravenna continued faithful to the emperor; but most of the cities of Romagna belonging to the exarchate, and all those of Pentapolis or La Marca d'Ancona, abhorring the emperor as an heretic, submitted to Luitprand king of the Lombards; who, pretending a zeal for the Catholic religion, took care to improve the discontent of the people to his advantage, by representing to them, that they could never maintain their religious rights under a prince, who was not only an heretic, but a persecutor of the orthodox.

In Naples, Exhilaratus, duke of that city, having received peremptory orders from the emperor to cause his edict to be put in execution, did all that lay in his power to persuade the people to receive it; but finding all his endeavours thwarted by the bishop of Rome, for whom the Neapolitans had a great veneration, he hired assassins to murder him. But the plot being discovered, though carried on with great secrecy, the Neapolitans, highly provoked against the duke, tore both him and his son to pieces, and likewise put to death one of his chief officers, who had composed a libel against the pope. Luitprand, and Gregory at that time duke of Benevento, laying hold of so favourable an opportunity to make themselves masters of the dukedom of Naples, did all that lay in their power to persuade the Neapolitans to submit to them. But the Neapolitans, bearing an irreconcilable hatred to the Lombards, with whom they had been constantly at variance, rejected every overture of that nature with the utmost indignation; and, continuing steadfast in their allegiance to Leo, received from Constantinople one Peter, who was sent to govern them in the room of Exhilaratus. Some writers suppose the Neapolitans, in this general revolt of the cities of Italy, to have shaken off the yoke with the rest, and to have appointed magistrates of their own election to govern them, in the room of the officers hitherto sent from Constantinople, or named by the exarch: but they are certainly mistaken; it being manifest from history, that Peter succeeded Exhilaratus in that dukedom, and that the Neapolitans continued to live under the emperors, till they were conquered many years after by the Normans.

In the mean time, Leo hearing of the murder of the exarch, and the general revolt of the cities, and not doubting but the pope was the chief author of so much mischief, sent the eunuch Eutychius into Italy, with the title and authority of *exarch*, strictly enjoining him to get the pope dispatched by some means or other, since his death was absolutely necessary for the tranquillity of Italy. The exarch spared no pains to get the pope into his power: but a messenger, whom

he had sent to Rome, being apprehended by the citizens, and an order from the emperor being found upon him to all his officers in that city, commanding them to put the pope to death at all events, the pope's friends thereforth guarded him with such care, that the exarch's emissaries could never afterwards find an opportunity of executing their design. As for the messenger, the Romans were for putting him to death; but the pope interposed, contenting himself with communicating the exarch.

And now the Romans, provoked more than ever against Leo, and, on the other hand, unwilling to live under the Lombards, resolved to revolt from the emperor, and appoint their own magistrates, keeping themselves united under the pope, not yet as their prince, but only as their head. This they did accordingly; and from these slender beginnings the sovereignty of the popes in Italy took its rise, though they did not then, as is commonly supposed by historians, but many years after, become sovereign lords of Rome.

Eutychius failed in his design upon the life of the pope; but having brought with him from Constantinople a good number of troops, he easily quelled the rebellion in Ravenna, and severely punished the authors of the late disturbances. As for the rebellious Romans, he was well apprised he could never reduce them, so long as they were supported by the king of the Lombards; and therefore he employed all his art and policy to take off that prince from the party of the Romans, and bring him over to his own.

Luitprand, for some time, withstood all his offers; but Thrafrimund duke of Spolito revolting at this very juncture, the exarch, laying hold of that opportunity, offered to assist the king with all his strength against the rebellious duke, provided he would, in like manner, assist him against the pope and the Romans. With this proposal Luitprand readily closed; and a league being concluded upon these terms between him and the exarch, the two armies joined, and began their march towards Spolito. At their approach, the duke, despairing of being able to resist two such powers, came out with a small attendance to meet them, and, throwing himself at the king's feet, sued, in that humble posture, for pardon; which Luitprand not only granted him, but confirmed him in the dukedom, after he had obliged him to take a new oath of allegiance, and give hostages for his fidelity in time to come. From Spolito, the two armies marched, in pursuance of the treaty, to Rome; and encamped in the meadows of Nero, between the Tiber and the Vatican.

Gregory had caused the city of Rome to be fortified in the best manner he could: but being sensible that the Romans alone could not long hold out against two such armies, and reflecting on the kind treatment the duke of Spolito had met with upon his submitting to the king, he resolved to follow his example; and accordingly, taking with him some of the clergy, and the principal inhabitants of the city, he went to wait on the king in his camp; and there, with a pathetic speech, as he was a great master of eloquence, softened Luitprand to such a degree, that, throwing himself at his feet in the presence of the whole army, he begged pardon for entering into an alliance against him;

Lombards. him : and, assuring him of his protection for the future, he went with him to the church of St Peter ; and there, disarming himself in the presence of his chief officers, he laid his girdle, his sword, and his gantlet, with his royal mantle, his crown of gold, and crofs of silver, on the apostle's fepulchre. After this, he reconciled the pope with the exarch, who was thereupon received into the city, where he continued for some time, maintaining a friendly correspondence with the pope. At this time an impostor, taking the name of *Tiberius*, and pretending to be defended from the emperors, seduced a great many people in Tuscany, and was by them proclaimed emperor. The exarch resolved to march against him ; but as he had not sufficient forces to oppose the rebels, Gregory, who let no opportunity slip of obliging Leo, persuaded the Romans to attend the exarch in this expedition ; by which means the usurper being taken in a castle, his head was sent to the emperor, and the rebellion utterly suppressed. But the emperor still insisting upon his edict against the images being received in Rome, the Romans, at the instigation of the pope, publicly renounced their allegiance to Leo, paid him no more tribute, and withdrew for ever their obedience to the emperors of the East.

20 The emperor seizes the dominions of the pope. Leo, informed of this revolt, and not questioning but the pope was the author of it, immediately caused all the patrimonies of the church of Rome in Sicily, Calabria, and his other dominions, to be confiscated. At the same time, he ordered a powerful army to be raised, with a design to recover the towns that had revolted ; to chastise the Romans for their rebellion ; and, above all, to be revenged on the pope, who had raised all these disturbances, by opposing himself, and persuading others to oppose, the execution of his edict. Gregory, alarmed at the warlike preparations that were carrying on throughout the empire, and well apprised that they were chiefly designed against him and the Romans, resolved to recur to the protection of the French, the only nation at that time capable of coping with the emperor, and on whom, on account of their zeal for religion, he thought he might depend. The Lombards were then very powerful ; but, as they wanted to be masters of Rome, he did not think it advisable to trust them. The Venetians, though zealous in the defence of the pope, were not yet in a condition to withstand the power of the emperor ; and, besides, were jealous of the Lombards, who watched all opportunities of enlarging their dominions at the expence of their neighbours. As for Spain, it was then in a most deplorable condition, being over-run, and almost wholly ruined, by the Saracens.

21 Who supplies to the French. The French nation was at this time governed by the celebrated Charles Martel, who had distinguished himself in a most eminent manner in the wars of France and Germany ; and had, not long before, gained a signal victory over the Saracens in the neighbourhood of Tours ; whence he was generally reputed the best commander, and the greatest hero, of his time. To him, therefore, Gregory sent a solemn embassy, with a great number of relies, earnestly intreating him to take the Romans, and the church, under his protection, and defend them against the attempts of Leo. The ambassadors were received with

extraordinary marks of honour ; and a treaty was soon concluded between them and Charles, who engaged to march into Italy in person, at the head of a powerful army, in defence of the Romans and the church, if they should be attacked either by the emperor or the Lombards. On the other hand, the Romans were to acknowledge him for their protector, and confer on him the honour of the consulship, as it had been formerly conferred on Clovis by the emperor Anastasius, after that prince had defeated the Visigoths. The ambassadors returned from France loaded with rich presents. But Gregory did not long enjoy the fruit of their negotiations ; for he died the same year 731, and was succeeded by Gregory III. in whose time some place the above-mentioned embassy.

22 End of the Lombard monarchy. The French nation was at this time just recovered from its distressed situation under the descendants of Clovis ; and by the bravery and conduct of Charles Martel, had become the most powerful kingdom in the west. His successor Pepin was no less wise and powerful than his father had been ; and as the ambition of the Lombard princes would be satisfied with nothing less than the entire conquest of Italy, the French monarch, Charlemagne, under colour of assisting the pope, at last put an end to the empire of Lombardy, as related under the article FRANCE, n^o 21, 22.

23 Character of the Lombards. The Lombards were at first a cruel and barbarous nation ; but divesting themselves by degrees of their native fierceness and barbarity, especially after they had embraced the Christian religion, they governed with such equity and moderation, that most other nations envied the happiness of those who lived under them. Under the government of the Lombards (says Paulus Diaconus) no violence was committed, no one unjustly dispossessed of his property, none oppressed with taxes ; theft, robberies, murder, and adultery, were seldom heard of : every one went, without the least apprehension, wherever he pleased. Their laws were so just and equitable, that they were retained in Italy, and observed there some ages after their kingdom was at an end.—According to Paulus Diaconus, also, their dress was loose, and for the most part of linen, such as the Anglo-Saxons wore, being interwoven with various colours ; that their shoes were open to the end of their foot, and that they used to button or lace them. From some ancient paintings, it appears, that they shaved the back part of their heads, but that their hair was long before ; their locks being parted, and laid on each side their foreheads.

LOMBARD, or LOMBART (Peter), an engraver of considerable eminence, who flourished about the year 1660. He was a native of Paris, where he learned the art of engraving. It appears that he came into England before the revolution, because some of his plates for English publications are dated prior to that event. He executed a vast variety of plates, as well historical as emblematical ; which, however, were chiefly for books. But his best works are portraits ; and of these he produced a considerable number, which are esteemed. They are mostly after Vandyck.—He also engraved historical subjects, from Poussin, Raphael, Annibal Caracci, Guido, and other masters.

colour used by painters), the name of the 33d order in Linnaeus's *Fragments of a Natural Method*, consisting of the following genera, many of which furnish beautiful tinctures that are used in dyeing, viz. *adenanthera*, *baubinia*, *caesalpinia*, *caffia*, *ceratonia*, *cercis*, *gleditria*, *guilandina*, *hamatoxylon*, *hymenaea*, *mimosa*, *parkinsonia*, *poinciana*, *polygama*. See BOTANY, p. 464.

LOCH-LOMOND, a large lake of Dunbarton or Lennox-shire in Scotland, of which Mr Pennant gives the following description. "Loch-lomond, the lust, the most beautiful of the Caledonian lakes. The first view of it from Tarbat presents an extensive serpentine winding amidst lofty hills; on the north, barren, black, and rocky, which darken with their shade that contracted part of the water. On the west side, the mountains are clothed near the bottoms with woods of oak quite to the water-edge; their summits lofty, naked, and craggy. On the east side, the mountains are equally high; but the tops form a more even ridge parallel to the lake, except where Ben-lomond, like Saul amidst his companions, overtops the rest. The upper parts were black and barren; the lower had great marks of fertility, or at least of industry, for the yellow corn was finely contrasted with the verdure of the groves intermixed with it.

"This eastern boundary is part of the Grampian hills, which extend from hence through the counties of Perth, Angus, Mearns, and Aberdeen. The road runs sometimes through woods, at others is exposed and naked; in some, so steep as to require the support of a wall; the whole the work of the soldiery: blessed exchange of instruments of destruction for those that give safety to the traveller, and a polish to the once inaccessible native! Two great head-lands covered with trees separate the first scene from one totally different; the last is called the *Point of Firkin*. On passing this cape an expanse of water bursts at once on your eye, varied with all the softer beauties of nature. Immediately beneath is a flat covered with wood and corn; beyond, the headlands stretch far into the water, and consist of gentle ridings; many have their surfaces covered with wood, others adorned with trees loosely scattered either over a fine verdure or the purple bloom of the heath. Numbers of islands are dispersed over the lake, of the same elevated form as the little capes, and wooded in the same manner; others just peep above the surface, and are tufted with trees; and numbers are so disposed as to form magnificent vistas between.

"Opposite Lufs, at a small distance from shore, is a mountainous isle almost covered with wood; is near half a mile long, and has a most fine effect. I could not count the number of islands, but was told there are 28; the largest two miles long, and stocked with deer.

"The length of this charming lake is 24 Scotch miles; its greatest breadth 8; its greatest depth, which is between the point of Firkin and Ben-lomond, is 120 fathoms. Besides the fish common to the lochs are guinaiads, called here *poans*.

"The surface of Loch-lomond has for several years past been observed gradually to increase, and invade the adjacent shore: and there is reason to suppose that churches, houses, and other buildings, have been lost

in the water. Near Lufs is a large heap of stones at a distance from the shore, known by the name of the old church; and about a mile to the south of that, in the middle of a large bay, between Camitradan and the isle Inch-lavanack, is another heap, said to have been the ruins of a house. To confirm this, it is evident by a passage in Camden's *Atlas Britannica*, that an island, existing in his time, is now lost; for he speaks of the isle of Camitradan, placed between the lands of the same name and Inch-lavanack, in which, adds he, was an house and orchard. Besides this proof, large trees with their branches still adhering are frequently found in the mud near the shore, overwhelmed in former times by the increase of water. This is supposed to be occasioned by the vast quantities of stone and gravel that are continually brought down by the mountain rivers, and by the falls of the banks of the Leven; the silt filling the bed of the lake, the silt impeding its discharge through the bed of the river."

LOMONOZOF, a celebrated Russian poet, the great refiner of his native tongue, was the son of a person who trafficked in fish at Kolmogori: he was born in 1711, and was fortunately taught to read; a rare instance for a person of so low a station in Russia. His natural genius for poetry was first kindled by the perusal of the Song of Solomon, done into verse by Polotki, whose rude composition, perhaps scarcely superior to our version of the psalms by Sternhold and Hopkins, inspired him with such an irresistible passion for the muses, that he fled from his father, who was desirous of compelling him to marry, and took refuge in the Kaikonoispalski monastery at Moscow; there he had an opportunity of indulging his taste for letters, and of studying the Greek and Latin languages. In this seminary he made so considerable a progress in polite literature, as to be noticed and employed by the Imperial academy of sciences. In 1736 he was sent at the expense of that society, to the university of Marburgh in Hesse Cassel, where he became a scholar of the celebrated Christian Wolf, under whom he studied universal grammar, rhetoric, and philosophy. He continued at Marburgh four years, during which time he applied himself with indefatigable diligence to chemistry, which he afterwards pursued with still greater success under the famous Henckel at Freyberg in Saxony. In 1741 he returned into Russia; was chosen in 1742 adjunct to the imperial academy; and in the ensuing year member of that society and professor of chemistry. In 1760 he was appointed inspector of the seminary, then annexed to the academy; in 1764 he was gratified by the present empress with the title of counsellor of state; and died April 4th that year, in the 54th year of his age. Lomonozof excelled in various kinds of composition; but his chief merit, by which he bears the first rank among the Russian writers, is derived from his poetical compositions, the finest of which are his odes. The first was written in 1739, while he studied in Germany, upon the taking of Kotlichin, a fortress of Crim. Tartary, by Marshal Munich. The odes of Lomonozof are greatly admired for originality of invention, sublimity of sentiment, and energy of language; and compensate for the turpid style which, in some instances, have been imputed to them, by that spirit and fire which are the prin-

Lomonozof,
London.

principal characteristics in this species of composition. Pindar was his great model; and if we may give credit to a person well versed in the Russian tongue, he has succeeded in this daring attempt to imitate the Theban bard, without incurring the censure of Horace. In this, as well as several other species of composition, he enriched his native language with various kinds of metre, and seems to have merited the appellation bestowed upon him of the *Father of Russian Poetry*. A brief recapitulation of the principal works of Lomonozof, which were printed in three volumes octavo, will serve to show the versatility of his genius, and his extensive knowledge in various branches of literature. The first volume, beside a Preface on the advantages derived to the Russian tongue from the ecclesiastical writings, contains ten sacred and nineteen panegyric odes, and several occasional pieces of poetry. The second comprises An Essay in Prose on the Rules for Russian Poetry; Translation of a German Ode; Idylls; Tamira and Selim, a tragedy; Demophoon, a tragedy; Poetical Epistle on the Utility of Glais; two cantos of an epic poem, intitled, Peter the Great; A Congratulatory Copy of Verses; An Ode; Translation of Baptiste Rousseau's Ode *Sur le Bonheur*; Heads of a Course of Lectures on Natural Philosophy; certain passages translated in verse and prose, according to the original, from Cicero, Erasmus, Lucian, Elian, Ammianus Marcellinus, Quintus Curtius, Homer, Virgil, Martial, Ovid, Horace, and Seneca, which Russian translations were brought as examples in his Lectures upon Rhetoric; lastly, Description of the Comet which appeared in 1744. The third volume consists chiefly of Speeches and Treatises read before the Academy; Panegyric on the Empress Elizabeth; on Peter the Great; Treatise on the Advantages of Chemistry; on the Phenomena of the Air occasioned by the Electrical Fire, with a Latin translation of the same; on the Origin of Light as a new Theory of Colours; Methods to determine with precision the Course of a Vessel; on the Origin of Metals by the means of Earthquakes; Latin Dissertation on Solidity and Fluidity; on the Transit of Venus in 1761, with a German translation. Beside these various subjects, Lomonozof made no inconsiderable figure in history, having published two small works relative to that of his own country. The first, styled Annals of the Russian Sovereigns, is a short chronology of the Russian monarchs; and the second is, the Ancient History of Russia, from the Origin of that Nation to the Death of the Great Duke Yaroslav I. in 1054; a performance of great merit, as it illustrates the most difficult and obscure period in the annals of this country.

LONDON, a large city of Middlesex in England, the metropolis of Great Britain, and one of the most wealthy and populous places in the world, is situated on the river Thames, in 51° 31' north latitude, 400 miles south of Edinburgh, and 270 south-east of Dublin; 180 miles west of Amsterdam, 210 north-west of Paris, 500 south-west of Copenhagen, 600 north-west of Vienna, 790 south-west of Stockholm, 800 north-east of Madrid, 820 north-west of Rome, 850 north-east of Lisbon, 1360 north-west of Constantinople, and 1414 south-west of Moscow.

This city was by the Romans first called *Londinium* or *Lundinium*, as we find it in Tacitus, Ptolemy, An-
N° 186.

London.

toninus, and Ammianus. That name was afterwards changed into *Agylla* in honour, as some say, of Helena Augusta, the mother of Constantine the Great; while others think it more probable that it had this name from the second legion, whose peculiar title was *Augusta*; and some imagine that the honourable appellation of *Augusta* was conferred upon this city by the Romans, as upon other principal cities of their empire, on account of its being grown up to be the capital of their British province. How long the name of *Augusta* prevailed, is not now certainly known; but after the establishment of the Saxons we find no more mention of *Augusta*. It was then called *Caer Lundain*, *Lundon Byrig*, *Lunden Caester*, *Lunden-zyge*, *Lundenne*, *Lunden-berb*, or *Lundenburg*; since the conquest the records call it *Londinia*, *Lundonia*, *Londine*, *Londres*; and, for several ages past, it has been called *London*, a manifest corruption from Tacitus's *Londinium*. The most probable derivation of these names appears to be, either from the British words *llong* "a ship," and *din* "a town," i. e. a town or harbour for ships; or from *Llin* "a lake," i. e. *Llin din*, "the town upon the lake," the Surry side being supposed, upon very probable grounds, to have been anciently a great expanse of water.

Londinium, however, was not the primitive name of this famous place, which existed before the invasion of the Romans; being, at the time of Caesar's arrival in the island, the capital of the *Trinobantes* or *Trinou-ats*. The name of this nation, as appears from Baxter's British Glossary, was derived from the three following British words, *tri*, *nou*, *bant*, which signify the "inhabitants of the new city." This name, it is supposed, might have been given them by their neighbours, on account of their having newly come from the continent into Britain, and having there founded a city called *tri-nou*, or the "new city;" the most ancient name of the renowned metropolis of Britain. The *Trinobantes* had come so lately from Belgium, that they seem scarcely to have been firmly established in Britain at the time of the first Roman invasion: For their new city, which soon after became so famous, was then so inconsiderable, that it is not mentioned by Caesar, tho' he must have been within sight of the place where it was situated. His silence about this place, indeed, is brought as a proof that he did not cross the Thames; while Norden by the *firmissima civitas* of the *Trinobantes* understands the city in question the *Trinobantes* themselves having been among the first of the British states who submitted to that conqueror.

By Ptolemy, and some other ancient writers of good authority, indeed, *Londinium* is placed in Cantium, or Cent, on the fourth side of the Thames; and it is the opinion of some moderns, that the Romans probably had a station there, to secure their conquests on that side of the river, before they reduced the *Trinobantes*. The place fixed upon for this station is St George's field, a large plot of ground situated between Lambeth and Southwark, where many Roman coins, bricks, and chequered pavements, have been found. Three Roman ways from Kent, Surry, and Middlesex, intersected each other in this place: this therefore is supposed to be the original *Londinum*, which it is thought became neglected after the Romans reduced the *Trinobantes*, and settled on the other
3 side

When founded.

Henry's Hist. vol. 5. p. 170.

² London. side of the Thames; and the name was transferred to the new city.

The situation of this city, as Mr Pennant observes, was just such as the people would select according to the rule established among the Britons. An immense forest originally extended to the river-side, and even as late as the reign of Henry II. covered the northern neighbourhood of the city, and was filled with various species of beasts of chase. It was defended naturally by fosses; one formed by the creek which run along Fleet-ditch, the other afterwards known by that of Walbrook; the south side was guarded by the Thames; the north they might think sufficiently protected by the adjacent forest.

³ When taken possession of by the Romans.

The Romans possessed themselves of London, on their second invasion in the reign of Claudius, about 105 years after their first under Cæsar. They had begun with Camalodunum, the present Maldon in Essex; and having taken it, planted there a colony consisting of veterans of the 14th legion. London and Verulam were next taken possession of about one and the same time. Camalodunum was made a *colonia*, or place governed entirely by Roman laws and customs; Verulam (on the site of which St Alban's now stands), a *municipium*, in which the natives were honoured with the privileges of Roman citizens, and enjoyed their own laws and constitutions; and Londinium only a *prefectura*, the inhabitants, a mixture of Romans and Britons, being suffered to enjoy no more than the name of citizens of Rome, being governed by Prefects sent annually from thence, without having either their own laws or magistrates. "It was even then of such concourse (says Mr Pennant), and such vast trade, that the wise conquerors did not think fit to trust the inhabitants with the same privileges as other places of which they had less reason to be jealous." But others observe, that this is a mistake; and that the Romans, in order to secure their conquest, and to gain the affections of those Britons who had already submitted to their authority, made London equally a *municipium* or free city with Verulamium, as may be seen by referring to Aulus Gellius, l. 16. c. 13. and to Spanhem. orbis Roman. p. 37, 38. tom. ii.

⁴ Ancient commerce of London.

It is difficult to say what were the particular articles of commerce exported from and imported into the port of London at this period. The imports and exports of the island in general we know: Strabo says, "Britain produceth corn, cattle, gold, silver, iron; besides which, skins, slaves, and dogs naturally excellent hunters, are exported from that island." It is probable that the two first and three last articles were exported from London; and perhaps, too, the *gagates* or jet-stone mentioned by Solinus as one of the productions of Britain, together with horses, were exported from thence. The imports were at first salt, earthen ware, and works in brass, polished bits of bones emulating ivory, horse-collars, toys of amber, glasses, and other articles of the same material.

In the reign of Nero, as Tacitus informs us, London was become a city highly famous for the great conflux of merchants, her extensive commerce, and plenty of all things. No fewer than seven of the fourteen itinera of Antoninus begin or end at London; which tends to corroborate the many proofs

which might be adduced, that this city was the capital of Britain in the Roman times.

At first London had no walls or other fortifications ⁵ when first to defend it, and was therefore exposed to the attacks of every enemy, and thus it suffered severely about the year 64, being burnt by the Britons under Boadicea, and all the inhabitants massacred. But it was soon restored by the Romans; and increased so much, that in the reign of the emperor Severus it is called by Herodian a *great and wealthy city*. It continued, however, in a defenceless state for more than a century after this last period; when at last a wall of hewn stone and British bricks was erected round it.

London at this time extended in length from Ludgate-hill to a spot a little beyond the Tower. The breadth was not half equal to the length, and at each end grew considerably narrower. Maitland ascribes the building of the walls to Theodosius governor of Britain in 369. Dr Woodward, with more probability, supposes them to have been founded under the auspices of Constantine the Great; and this seems to be confirmed by the numbers of coins of that emperor's mother Helena, which have been discovered under them, placed there by him in compliment to her. The same emperor made it a bishop's see; for it appears that the bishops of London and York, and another English bishop, were at the council of Ailes in the year 314; he also settled a mint in it, as is plain from some of his coins. The ancient course of the wall was as follows: It began with a fort near the present site of the Tower, was continued along the Minories, and the back of Houndditch, across Bishopgate-street, in a straight line by London-wall to Cripple-gate; then returned southward by Crowder's Well Alley, (where several remnants of lofty towers were lately to be seen) to Aldersgate; thence along the back of Bull and Mouth-street to Newgate, and again along the back of the houses in the Old Bailey to Ludgate; soon after which it probably finished with another fort, where the house, late the king's printing house, in Black Friars, now stands: from hence another wall ran near the river side, along Thames-street, quite to the fort on the eastern extremity. The walls were three miles a hundred and sixty-five feet in circumference, guarded at proper distances on the land side with fifteen lofty towers; some of them were remaining within these few years, and possibly may still Maitland mentions one twenty-six feet high, near Gravel-lane, on the west side of Houndditch; another, about eighty paces south-east towards Aldgate; and the bases of another, supporting a modern house, at the lower end of the street called the Vineyard, south of Aldgate. The walls, when perfect, are supposed to have been twenty-two feet high, the towers forty. These, with the remnants of the wall, proved the Roman structure, by the tiles and disposition of the masonry. London-wall, near Moorfields, is now the most entire part left of that ancient precinct. The gates, which received the great military roads, were four. The Prætorian way, the Saxon Watling street, passed under one, on the site of the late Newgate; vestiges having been discovered of the road in digging above Holburn-bridge: it turned down to Dowgate, or more properly Dwr-gate or Water-gate, where

⁶ Their ancient course, &c.

^{London,} there was a trajectus or ferry, to join it to the Watling-street, which was continued to Dover. The Hermin street passed under Cripplegate; and a vicinal way went under Aldgate by Bethnal-green, towards Oldford, a pafs over the river Lee to Duroleiton, the modern Leiton in Effex.

^{London} After the Romans deferred Britain, a new and fierce race fucceeded. The Saxons, under their leaders Hengist and Horsa, landed in 448, having been invited over by the provincials as auxiliaries against the Scots and Picts; but quarrelling with their friends, they found means to establish themselves in the island, and in procefs of time entirely subdued them, as related under the article ENGLAND, n° 31—44. ^{London} fell into the hands of those invaders about the year 457; and became the chief city of the Saxon kingdom in Effex. It suffered much in the wars carried on between the Britons and Saxons: but it soon recovered; so that Bede calls it a *princely mart-town*, under the government of a chief magistrate, whose title of *portgrave*, or *portreeve* (for we find him called by both names), conveys a grand idea of the mercantile state of London in those early ages, that required a governor or guardian of the port. During the civil wars of the Saxons with each other, the Londoners had always the address to keep themselves neuter; and about the year 819, when all the seven Saxon kingdoms fell under the power of Egbert, London became the metropolis of England, which it has ever since continued.

^{Plundered by the Danes.} During the invasions of the Danes, London suffered greatly. In 849, these invaders entered the Thames with 250 ships, plundered and burnt the city, and massacred the inhabitants; and two years after they returned with a fleet of 350 sail, fully determined to destroy every thing that had escaped their barbarity in the former expedition. At this time, however, they were disappointed; most of their troops being cut in pieces by king Ethelwolf and his son Athelbald; yet such was the destruction made by those barbarians at London, that it suffered more from these two incursions than ever it had done before.

^{Recovers under Alfred the Great.} In the reign of king Alfred the Great, London began to recover from its former ruinous state. He rebuilt its walls, drove out the Danish inhabitants who had settled there, restored the city to its former liberties and beauty, and committed the care of it to his son-in-law, Elthelred duke of Mercia, in hopes that this might always be a place of secure retreat within its strong walls, whatever might happen from a foreign or domestic enemy. In 893, however, he had the mortification to see his capital totally reduced to ashes by an accidental fire, which could not be extinguished, as the houses at that time were all built of wood. The walls, however, being constructed of incombustible materials, continued to afford the same protection as before; the houses were quickly rebuilt, and the city divided into wards and precincts for its better order and government. This king also instituted the office of sheriff, the nature of which office made it necessary to have it also in London: so that here we have the glimmerings of the order of magistrates afterwards settled in the city of London; in the person of the portreeve, or portgrave, or governor of the city, as supreme magistrate; in the sheriff, and in the officer or subordi-

^{London,} nate magistrate by what name soever then distinguished, which, being placed at the head of each ward or precinct, were analogous to the more modern title of *aldermen* and *common-council men*.

^{Brick and stone houses first erected.} Alfred having settled the affairs of England in the most prudent manner, directed his attention to the ornamenting, as much as possible, the city of London. For this purpose, he spirited up the English to an emulation in building their houses of stronger and more durable materials than formerly. At that time their houses were mostly of wood; and an house built of any other materials was looked upon as a kind of wonder. But Alfred having begun to raise his palaces of stone and brick, the opulent Londoners, and the nobility resident in and about London, followed the example, though the custom did not come into general use till some ages after.

^{Defeated by Canute.} In 1015, a foreign enemy again appeared before London. Canute king of Denmark having invaded and plundered the counties of Dorset, Somerset, and Wilts, sailed up the Thames with 200 ships, and laid siege to the city. The citizens continued faithful, notwithstanding the defection of the greatest part of the kingdom; and made such a brave resistance, that Canute thought fit to withdraw his army, leaving only his fleet to blockade the city by water, that when he found a fair opportunity he might renew the siege with better success. At last, however, being defeated in several battles by Edmund Ironside, he was obliged to call off his ships to cover his own army in case of necessity. In the compromise, however, which was afterwards made between Edmund and Canute, the city of London was given to the latter, and owned him for its lawful sovereign. We have a strong proof of the opulence of London even at this time, from the tax laid upon it by Canute in order to pay his army; this being no less than 105,000 l. while the rest of the nation was at the same time taxed only at 72,000 l.

^{Sends representatives to parliament.} In 1046, we have the first instance of the Londoners sending representatives to parliament. This happened on settling the succession to the throne after Canute's death. The English in general declared for Edward son of king Ethelred; or, if that could not be carried, for Hardicanute, son of Canute by queen Emma, and then absent on a tour to Denmark. The city of London espoused the claim and interest of Harold Harefoot, son also of Canute, by queen Elgiva of Northampton. Edward's party soon declined; and the Londoners agreed, for the peace of the realm, that the two brothers should divide the kingdom between them; but as Hardicanute did not return in proper time to England, a *witnensage-mote* was held at Oxford, where earl Leofrie, and most of the thanes on the north of the Thames, with the pilots of London, chose Harold for their king. Here, by pilots we are to understand the directors, magistrates, or leading men of the city: and this manifestly shows, that London was then of such consequence, that no important national affair was transacted without the consent of the inhabitants; for the Saxon annals assure us, that none were admitted into this assembly of election but the nobility and the pilots of London.

^{Suffers greatly by fires, hurricanes, &c.} On the invasion of the Normans under William I. London submitted as well as the rest of the kingdom; and received two charters from that prince, confirming

London. ing all the privileges they had under the Saxon kings, and adding several new ones. But while the citizens were promising themselves all manner of security and tranquillity under the new government, it was almost entirely reduced to ashes by an accidental fire in 1077. It had scarcely recovered from this calamity, when it was visited by another of the same kind in 1086, which began at Ludgate, and destroyed the best and most opulent part of the city; consuming, among other buildings, the cathedral of St Paul's; which, however, was soon rebuilt more magnificently than before. Under the reign of William Rufus, London suffered considerably by fires, hurricanes, and inundations, and seems to have been depressed by the tyranny of that prince; but Henry I. granted large immunities to the city, which again revived its trade, and was favourable to the progress of the arts. The king, however, still retained the privilege of appointing the portreeve, or chief magistrate; but the immunities granted to the Londoners secured their affections, and tended much to secure him on the throne. At the same time, there was such a plenty of all kinds of provisions, that as much corn was sold for 1s. as would suffice 100 people for a day; 4d. would purchase as much hay and corn as would maintain 20 horses for a day; and a sheep could be bought for a groat.

26
Monstrous
licentious-
ness of the
Normans.

Henry thought proper also to check the licentious behaviour of the Normans, which, by the favour showed them under the two Williams, had carried them into the most barbarous practices. Those who followed William Rufus in his excursions, harassed and plundered the country at discretion. Many of them were so extravagant in their barbarity, that what they could not eat or drink in their quarters, they either obliged the people to carry to market and sell for their use, or else they would throw it into the fire: and, at their going off, they frequently washed their horses heels with the drink, and flaved the calks containing the remainder. King Henry resolved to put a stop to these excesses and savage customs; and therefore published a proclamation at London, commanding that thenceforward all persons who should be convicted of such barbarities should have their eyes pulled out, or their hands or feet cut off, as the ministers of justice should think fit. This effectually checked the insolence of the Normans, and the city continued to flourish throughout the reigns of Henry I. and Stephen. The attachment of the citizens to Stephen, however, was a crime which never could be forgiven by Henry II. and, of consequence, he made them sensible of his displeasure, by making frequent demands of money from them. About this time, indeed, the Londoners were arrived at such a pitch of licentiousness, that their prosperity seemed a curse rather than a blessing. The sons of the most eminent and wealthy citizens entered into a confederacy to commit burglaries, and to rob and murder all that came in their way in the night-time. The king took an opportunity from these irregularities to enrich himself. He demanded several loans and free gifts; till at last the Londoners, to prevent further inquiries into their conduct, paid into the exchequer 5000l. in three years. These disorders, however, were at last stopped by the execution of John Senex; who, though a very rich and reputable citizen,

17
of the
Londoners.

had engaged in these enterprizes. He offered 500 lb. weight of silver, a prodigious sum in those days, for his pardon, but was refused. The king, however, still continued to drain the citizens of their money by free gifts; and at last fined every separate guild, fraternity, or company, that had presumed to act as bodies corporate without the royal letters-patent.

On the death of Henry II. the title of the first magistrate of London was changed from *portreeve* to that of *baillif*; and in 1189 claimed and acted in the office of the *chief bailif* at the coronation of Richard I. In 1191 this monarch permitted the bailiff, named *Henry Fitz Aulvine*, to assume the title of *mayor*. For, in 1192, we find certain orders of the mayor and aldermen to prevent fires; whereby it was ordained, that "all houses thereafter to be erected in London and the liberties thereof, should be built of stone, with party-walls of the same; and covered either with slates or tiles, to prevent those dreadful calamities by fire, which were frequently and chiefly occasioned by houses built of wood, and thatched with straw or reeds." And for this purpose, it was also provided by the discreeter men of the city, "that 12 aldermen of the city should be chosen in full hustings, and there sworn to assist the mayor in appeasing contentions that might arise among neighbours in the city upon inclosure betwixt land and land, and to regulate the dimensions of party-walls, which were to be of stone, 16 feet high and three feet thick; and to give directions about girders, windows, gutters, and wells." Such confidence also did Richard put in the wisdom and faithfulness of the city of London, that when it was resolved to fix a standard for weights and measures for the whole realm, his majesty committed the execution thereof to the sheriffs of London and Middlesex, whom he commanded to provide measures, gallons, iron rods, and weights for standards, to be sent to the several counties of England. This happened in 1193, at which time corn was advanced to the enormous price of 18s. 4d. per quarter.

The city of London was much favoured by King John, who granted them three charters soon after his accession. The first was a recital and confirmation of the privileges granted by Henry I. and II. with the farther privilege of being free from toll and every other duty or custom in his majesty's foreign dominions; for which they paid the sum of 3000 mēks. The second was a confirmation of one granted by King Richard. By this the citizens of London had the jurisdiction and conservancy of the river Thames; with a clause to extend that jurisdiction, and the powers therewith granted, to the river Medway; and with another clause to enable the said city, as conservators of the rivers Thames and Medway, to inflict a penalty of 10l. upon any person that should presume to erect a wear in either of these rivers. The third charter contains a fee-farm-rent of the sheriffwicks of London and Middlesex at the ancient rent, of which they had been deprived by Queen Maud; granting them also the additional power of choosing their own sheriffs. This charter was given by way of conveyance from the crown to the citizens for a valuable consideration, by which the sheriffwick became their freehold; and this is the first covenant or conveyance we find on record

London.

with the legal terms of *to have and to hold*, which are at this time accounted an essential part in all conveyances of property.

20
London op-
pressed by
Henry III.

During the reign of Henry III. the city of London was oppressed in many different ways. In 1218, he exacted a fine of 40 marks for selling a sort of cloth not two yards within the lints; and a 15th of the citizens personal estates for the enjoyment of their ancient rights and privileges. In 1221, he commanded by proclamation all the foreign merchants to depart the city; which drew 30 marks from the Anseatic company of the *Steelhard*, to have seisin of their guild or hall in Thames-street. But it was the wrestling-match at St Giles's in the fields that brought on their greatest burden. In the year 1221, on St James's day, the citizens of London having carried off the victory from the people of Westminster and other neighbouring villages, the steward of the abbot of Westminster, meditating revenge against the Londoners, proposed another wrestling-match with them, and gave a rain for the prize. The citizens resorted to the place at the time appointed; but were unexpectedly assaulted by a great number of armed men, who killed and wounded many, and dispersed the rest. This raised a great commotion in the city. The populace breathed revenge; and, by the instigation of Constantine Fitz-Arnuolph, a great favourite of the French party during the troubles in king John's reign, they proceeded to Westminster, and pulled down the houses both of the steward and abbot. Hearing afterwards that the abbot was come into the city with his complaint to Philip Daubney the king's counsellor, they pursued him, beat his servants cruelly, took away 12 of his horses, and would have murdered himself, had he not escaped by a back-door. Upon this tumult, Hubert de Bury, then chief justiciary, summoned the mayor and many of the principal citizens to attend him in the tower of London; and inquiring for the authors of the riot, Constantine, the ringleader, boldly answered, that "he was one; that they had done no more than they ought; and that they were resolved to avow what they had done, let the consequence be what it would." In this he was seconded by his nephew and one Geoffrey; but the justiciary, having dismissed all the rest, detained these three, and ordered them to be hanged next morning, though Constantine offered 15,000 marks for his pardon. Hubert then coming into the city with a strong guard, caused the hands and feet of most of the principal rioters he could seize to be cut off: all which was executed without any legal proceedings or form of trial. After these arbitrary cruelties, he degraded the mayor and all the magistrates; placed a *custos* over the city, and obliged 30 persons of his own choosing to become securities for the good behaviour of the whole city. Several thousand marks were also exacted by the king, before he would consent to a reconciliation.

This arbitrary behaviour alarmed the whole nation. The parliament of 1224 began to be uneasy for themselves, and addressed his majesty that he would be pleased to confirm the charter of liberties which he had sworn to observe; and the consequence of this application was a confirmation of the magna charta in the full parliament at Westminster in the year 1225. At this time also, the rights and privileges of the citizens

were confirmed. They were exempted from prosecutions for burles, *i. e.* lifted cloth; and were granted the right of having a common seal. The necessitous circumstances of this monarch, however, made him often exact money arbitrarily as long as he lived.

Under the succeeding reigns, as the liberty of the people in general was augmented, so the liberty, opulence, and power of the citizens of London increased, until they became a kind of balance to the power of the crown itself, which in some measure they still continue to be. Riots indeed, for which they generally suffered, were by no means unfrequent; the city often suffered by fires and plagues. Nothing, however, happened which materially affected the welfare of the city, till the reign of Charles II. in 1665.—This year London was ravaged by the most violent plague ever known in Britain. Dreadful
The whole summer had been remarkably still and plague in warm, so that the weather was sometimes suffocating,¹⁶⁶⁵⁻ even to people in perfect health; and by this unusual heat and sultry atmosphere, people were undoubtedly prepared for receiving the infection, which appeared with violence in the months of July, August, and September. A violent plague had raged in Holland in the year 1663; on which account the importation of merchandise from that country was prohibited by the British legislature in 1664. Notwithstanding this prohibition, however, it seems the plague had actually been imported; for in the close of the year 1664, two or three persons died suddenly in Westminster, with marks of the plague on their bodies. Some of their neighbours, terrified at the thoughts of their danger, removed into the city; but their removal proved too late for themselves, and fatal to those among whom they came to reside. They soon died of the plague; and communicated the infection to so many others, that it became impossible to extinguish the seeds of it by separating those that were infected from such as were not. It was confined, however, through a hard frosty winter, till the middle of February, when it again appeared in the parish of St Giles's, to which it had been originally brought; and after another long rest till April, showed its malignant force afresh, as soon as the warmth of the spring gave it opportunity.—At first, it took off one here and there, without any certain proof of their having infected each other, and houses began to be shut up, with a design to prevent its spreading. But it was now too late; the infection gained ground every day, and the shutting up of houses only made the diseases spread wider. People, afraid of being shut up, and sequestered from all communications with society, concealed their illness, or found means to escape from their places of confinement; while numbers expired in the greatest torments, destitute of every assistance; and many died both of the plague and other diseases, who would in all probability have recovered, had they been allowed their liberty, with proper exercise and air.—A house was shut up on account of a maid-servant, who had only spots, and not the gangrenous plague-blotches, upon her, so that her distemper was probably a petechial fever. She recovered; but the people of the house obtained no liberty to stir, either for air or exercise, for 40 days. The bad air, fear, anger, and vexation, attending this injurious treatment, cast the mistress of the family into a fever. The visitors appointed to
search

London.

London. search the houses, said it was the plague, though the physicians were of a different opinion: the family, however, were obliged to begin their quarantine anew, though it had been almost expired before; and this second confinement affected them so much, that most of the family fell sick, some of one distemper and some of another. Every illness that appeared in the family produced a fresh prolongation of their confinement; till at last the plague was actually brought in by some of those who came to inquire into the health of the family, and almost every person in the house died.—Many examples of a similar kind happened, and this was one of the worst consequences of shutting up houses. All means of putting a stop to the infection were evidently ineffectual. Multitudes fled into the country; many merchants, owners of ships, &c. shut themselves up, on board their vessels, being supplied with provisions from Greenwich, Woolwich, and single farm-houses on the Kentish side. Here, however, they were safe; for the infection never reached below Deptford, though the people went frequently on shore to the country-towns, villages, and farm-houses, to buy fresh provisions. As the violence of the plague increased, the ships which had families on board removed farther off; some went quite out to sea, and then put into such harbours and roads as they could best get at.

In the mean time, the distemper made the most rapid advances within the city. In the last week of July, the number of burials amounted to 2010; but the first week of August it rose to 3817; thence to 3880; then to 4237; the next week, to 6102; and at last to 7000 and 8000 weekly. In the last week of September, however, the fury of the disease began to abate; though vast numbers were sick, yet the number of burials decreased from 7155 to 5538; the next week there was a farther decrease to 4929, then to 4327, next to 2665, then to 1421, and the next week to 1031.

All this while, the poor people had been reduced to the greatest distresses, by reason of the stagnation of trade, and the sicknesses to which they were peculiarly liable on account of their manner of living. The rich, however, contributed to their subsistence in a most liberal manner. The sums collected on this occasion, are indeed almost incredible; being said to amount to 100,000*l.* per week. The king is reported to have contributed 1000*l.* weekly; and in the parish of Cripple-gate alone 17,000*l.* was distributed weekly among the poor inhabitants.—By the vigilance also of the magistrates, provisions continued remarkably cheap throughout the whole time of this dreadful calamity, so that all riots and tumults on that account were prevented; and at last, on the cessation of the disease in the winter of 1665, the inhabitants who had fled returned to their habitations, and London to appearance became as populous as ever, though it was computed that 100,000 persons had been carried off by the plague.

22
Account of
the great
Sic in 1666.

The city was scarcely recovered from the desolation occasioned by the plague, when it was almost totally laid in ashes by a most dreadful fire. This broke out in a baker's shop in Pudding-lane, on Saturday-night, September 2. 1666. In a few hours Billingsgate ward was entirely burnt down; and before morning the fire had crossed Thames-street, and destroyed the church of St

Magnus. From thence it proceeded to the bridge, and consumed a great pile of buildings there; but was stopped by the want of any thing more to destroy. The flames, however, being scattered by a strong east wind, continued their devastations in other quarters. All efforts to stop it proved unsuccessful throughout the Sunday. That day it proceeded up as far as Garlick-hitch; and destroying Canon-street, invaded Cornhill and the exchange. On Monday, the flames having proceeded eastward against the wind through Thames-street, invaded Tower-street, Grace-church-street, Fenchurch-street, Dowgate, Old-fish-street, Watling-street, Thread-needle-street, and several others, from all which it broke at once into Cheap-side. In a few hours Cheap-side was all in flames, the fire having reached it from so many places at once. The fire then continuing its course from the river on one side, and from Cheap-side on the other, surrounded the cathedral of St Paul's. This building stood by itself at some distance from any houses; yet such was the violence of the flames, and the heat of the atmosphere occasioned by them, that the cathedral took fire at top. The great beams and masonry stones broke through into Faith-church underneath, which was quickly set on fire; after which, the flames invaded Pater-noster-row, Newgate-street, the Old Bailey, Ludgate-hill, Fleet-street, Iron-monger-lane, Old-jury, Laurence-lane, Milk-street, Wood-street, Cutler-lane, Foster-lane, Lothbury, Cateaton-street; and, having destroyed Christ-church, burnt furiously through St Martin's Le Grand towards Aldersgate.

The fire had now attained its greatest extent, and was several miles in compass. The vast clouds of smoke obscured the sun so, that he either could not be seen at all, or appeared through it as red as blood. The flames reached an immense way up into the air, and their reflection from the smoke, which in the night-time seemed also like flame, made the appearance still more terrible. The atmosphere was illuminated to a great extent, and this illumination is said to have been visible as far as Jedburgh in Scotland. Some of the light ashes also are said to have been carried to the distance of 16 miles. Guildhall exhibited a singular appearance. The oak with which it was built was so solid that it would not flame, but burnt like charcoal, so that the building appeared for several hours like an enchanted palace of gold or burnished brass.

At last, on Wednesday morning, when every one expected that the suburbs as well as the city were to have been burnt, the fire began of itself to abate by reason of the wind having ceased, and some other changes no doubt taken place in the atmosphere. It was checked by the great building in Leaden-hall-street, and in other streets by the blowing up several houses with gun-powder; and on Thursday the flames were quite extinguished.—The following is a calculation of the damage done by this extraordinary conflagration.

	<i>£.</i>	<i>s.</i>	<i>d.</i>	Calculation of the damage done
Thirteen thousand two hundred houses, at 12 years purchase, supposing the rent of each 25 <i>l.</i> Sterling,	3,960,000	0	0

Wine, tobacco, sugar, &c. of which the town was at that time very full	1,500,000	0	0
	10,689,000	0	0

It was never certainly known whether this fire was accidental or designed. A suspicion fell upon the Papists; and this gained such general credit, that it is ascribed for a truth on the monument which is erected in memory of the conflagration. Of the truth of this assertion, however, though there was not sufficient proof, it had the effect of making the Papists most violently suspected and abhorred by the Protestants, which some time after proved very prejudicial to the city itself.

From this calamity, great as it was, London soon recovered itself, and became much more magnificent than before; the streets, which were formerly crooked and narrow, being now built wide and spacious; and the industry of its inhabitants repaired the losses they had sustained. In 1679, the city was again alarmed by the discovery of a design to destroy it by fire a second time. Elizabeth Oxley, servant to one Rind in Fetter-lane, having set her master's house on fire, was apprehended on suspicion, and confessed, that she had been hired to do it by one Stubbs a Papist, for a reward of 5l. Stubbs being taken into custody, acknowledged that he had persuaded her to it; and that he himself had been prevailed upon by one father Gifford his confessor, who had assured him, that by burning the houses of heretics he would do a great service to the church. He also owned that he had several conferences with Gifford and two Irishmen on the affair. The maid and Stubbs also agreed in declaring, that the Papists intended to rise in London, expecting to be powerfully supported by a French army. In consequence of this discovery, the Papists were banished from the city and ten miles round, and five Jesuits were hanged for the abovementioned plot.

The Papists thought to revenge themselves, by forging what was called the *meal-tub plot*, in which the

Presbyterians were supposed to hatch treacherous designs against the life of the king. Sir Edmondbury Godfrey also, who had been very active in his proceedings against the Papists, was murdered by some unknown persons; and this murder, together with their discovering the falsehood of the meal-tub plot, so exasperated the Londoners, that they resolved to show their detestation of Popery, by an extraordinary exhibition on the 17th of November, Queen Elizabeth's accession to the throne, on which day they had usually burnt the pope in effigy. The procession began with a person on horseback personating Sir Edmondbury Godfrey, attended by a bell-man proclaiming his execrable murder. He was followed by a person carrying a large silver cross, with priests in copes, Carmelites, and Gray-friars, followed by six Jesuits: then proceeded divers waiters, and after them some bishops with lawn-sleeves, and others with copes and mitres. Six cardinals preceded the pope, enthroned in a stately pageant, attended by divers boys with pots of incense, and the devil whispering in his ear. In this order they marched from Bishopsgate to Fleet-street; and there, amidst a great multitude of spectators, committed his holiness to the flames.

This procession gave great offence to the court, at which the duke of York, afterwards James II. had a great influence. The breach was farther widened by the choice of sheriffs for that year. The candidates set up by the court were rejected by a majority of almost two to one; but this did not deter their party from demanding a poll in their behalf, upon which a tumult ensued. This was represented by the Popish party in such colours to the king, that he issued out a commission that same evening for trying the rioters; which, however, was so far from intimidating the rest, that they grew more and more determined, not only to oppose the Popish party, but to exclude the duke of York from his succession to the crown.

In the mean time, the king prorogued the parliament, to prevent them from proceeding in their inquiry concerning the Popish plot, and the exclusion-bill. Upon this the lord-mayor, aldermen, and common-council, presented a petition to his majesty, in which they requested, that he would permit the parliament to sit in order to complete their salutary measures and councils. This petition was highly resented by the king; who, instead of granting it, dissolved the parliament, and could never afterwards be reconciled to the city. From this time it was determined to seize their charter; and fresh provocations having been given about the election of sheriffs, a *quo warranto* was at last produced by the attorney-general, in order to overthrow their charter, and thereby to deprive the citizens of the power to choose sheriffs, against the city. This information set forth, That "the mayor and commonalty and citizens of the city of London, by the space of a month then last past and more, used, and yet do claim to have and use, without any lawful warrant or regal grant, within the city of London aforesaid, and the liberties and privileges of the same city, the liberties and privileges following, viz. 1. To be of themselves a body corporate and politic, by the name of *mayor and commonalty and citizens of the city of London*. 2. To have *sheriffs civitatis et com. London. Et com. Middlesex*, and to name, make, and elect, and constitute

London.

constitute them. 3. That the mayor and aldermen of the said city should be justices of the peace, and hold sessions of the peace. All which liberties, privileges, and franchises, the said mayor and commonalty, and citizens of London, upon the king did by the space aforesaid usurp, and yet do usurp."

Though nothing could be more unjust than this prosecution, the ministry were determined at all events to crush the Londoners; rightly judging, that it would be an easy matter to make all other corporations surrender their charters into the king's hands, and that they had no other body in the nation to fear. Accordingly they displaced such judges as would not approve of their proceedings; and, on the 12th of June 1683, Justice Jones pronounced the following sentence: "That a city might forfeit its charter; that the malversations of the common-council were acts of the whole city; and that the points set forth in the pleadings were just grounds for the forfeiting of a charter."

Notwithstanding this sentence, however, the attorney-general, contrary to the usual custom in such cases, was directed to move that the judgment might not be recorded; being afraid of the consequences. Yet it was judged that the king might seize the liberties of the city. A common-council was immediately summoned to deliberate on this exigency. The country party moved to have the judgment entered; but they were over-ruled by the court-party, who insisted upon an absolute submission to the king before judgment was entered; and though this was in effect a voluntary surrender of the city liberties, and depriving themselves of the means of getting the judgment reversed, the act of submission was carried by a great majority: and in a petition from the lord-mayor, aldermen, and common-council, they "acknowledged their own misgovernment, and his majesty's lenity; begged his pardon, and promised constant loyalty and obedience; and humbly begged his majesty's commands and directions." To this his majesty answered, that he would not reject their suit, if they would agree upon the following particulars. 1. That no lord-mayor, sheriff, recorder, common serjeant, town-clerk, or coroner, of the city of London, or steward of the borough of Southwark, shall be capable of, or admitted to, the exercise of their respective offices before his majesty shall have approved of them under his sign manual. 2. That if his majesty shall disapprove the choice of any person to be lord mayor, and signify the same under his sign manual to the lord mayor, or, in default of a lord mayor, to the recorder or senior alderman, the citizens shall, within one week, proceed to a new choice: and if his majesty shall in like manner disapprove the second choice, his majesty may, if he pleases, nominate a person to be lord mayor for the year ensuing. 3. If his majesty shall, in like manner, disapprove the persons chosen to be sheriffs, or either of them, his majesty may appoint sheriffs for the year ensuing. 4. That the lord mayor and court of aldermen may, with the leave of his majesty, displace any alderman, recorder, &c. 5. Upon the election of an alderman, if the court of aldermen shall judge and declare the person presented to be unfit, the ward shall choose again; and upon a disapproval of a second choice, the court may appoint another in

his room. 6. That the justices of the peace should be by the king's commission; and the settling of those matters to be left to his majesty's attorney-general, and counsel learned in the law."

To these the lord keeper added, in the king's name, "That these regulations being made, his majesty would not only pardon this prosecution, but would confirm their charter in such a manner as should be consistent with them;" concluding thus: "My lord mayor, the term draws towards an end, and Midsummer-day is at hand, when some of the officers used to be chosen; whereof his majesty will reserve the approbation. Therefore, it is his majesty's pleasure, that you return to the city, and consult the common-council, that he may speedily know your resolutions thereupon, and accordingly give his directions. That you may see the king is in earnest, and the matter is not capable of delay, I am commanded to let you know he hath given orders to his attorney-general to enter upon judgment on Saturday next; unless you prevent it by your compliance in all these particulars."

A common-council was summoned, when the friends of liberty treated those slavish conditions as they deserved; and even declared, that they were ready to sacrifice all that was near or dear to them, rather than submit to such arbitrary impositions: but when it was put to the vote, there appeared a majority of 18 for submission.

Thus the king got the government of the city into his own hands, though he and his brothers entirely lost the affections of the Londoners. But, not content with their submission, his majesty departed from his promise; commanded the judgment upon the *quo warranto* to be entered; and commissioned Sir William Pritchard, the lord mayor, to hold the same office during his majesty's pleasure. In the same manner he appointed or displaced the other magistrates as he thought proper; after which the ministry, having nothing to fear, proceeded in the most arbitrary manner.

In this subjection to the will of the court, the city of London continued till the Revolution: but, in 1689, the immediate restoration of the Londoners to their franchises was ordered; and in such a manner and form, as to put it out of the powers of an arbitrary ministry and a corrupt judge and jury to deprive them of their chartered liberties for the time to come. Accordingly a bill was brought into parliament, and passed, for reversing the judgment of the *quo warranto* against the city of London, and for restoring the same to its ancient rights and privileges. Since that time the city of London hath enjoyed tranquillity; its commerce hath been carried to the highest pitch; and for the politeness, riches, and number of its inhabitants, as well as its extent and the magnificence of its buildings, is inferior to no city in Europe, if not superior to every one.

That part of this immense capital which is distinguished by the name of *The City*, stands on the north shore of the river, from the Tower to the Temple, occupying only that space formerly encompassed by the wall, which in circumference measures but three miles and 165 feet. In this wall there were seven gates by land, viz. Ludgate, Aldgate, Cripplegate, Aldersgate, Moorgate, Bishopgate, which were all taken down in September 1762; and Newgate, the county gaol, which was also taken down in 1776, and a massive building,

Description
of the city

London.

building erected a little south of it, which by the rioters in 1780 received damage to the amount of £.80,000. On the side of the water there were Dowgate and Billingsgate, long since demolished, as well as the postern-gate near the Tower. In the year 1670 there was a gate erected called Temple-Bar, which terminates the bounds of the city westward. The *hinteries*, or those parts of this great city which are subject to its jurisdiction and lie without the walls of London, are bounded on the east, in White-chapel, the Minories, and Bishopsgate, by bars, which were formerly posts and chains, that were frequently taken away by arbitrary power, when it was thought proper to seize the franchises of the city of London: on the north, they are bounded in the same manner in Pick-axe street, at the end of Fan-alley, and in St John's street: on the west, by bars in Holborn: at the east end of Middle Row, and at the west end of Fleet-street, by the gate called *Temple-Bar*, already mentioned: on the south, we may include the jurisdiction which the city holds on the river Thames, and over the borough of Southwark.

The city, including the borough, is at present divided into 26 wards.

31
Division in-
to wards.

1. *Aldersgate ward* takes its name from a city-gate which lately stood in the neighbourhood. It is bounded on the east by Cripplegate ward; on the west, by Farringdon ward within and without; and on the south, by Farringdon ward within. It is very large, and is divided into Aldersgate-within and Aldersgate-without. Each of these divisions consists of four precincts, under one alderman, eight common-council men, of whom two are the alderman's deputies, eight constables, fourteen inquest-men, eight scavengers, and a beadle; exclusive of the officers belonging to the liberty of St Martin's le Grand, which contains 168 houses.

2. *Aldgate* takes its name also from a gate, which was of great antiquity, being mentioned in king Edgar's charter to the knights of the Knighton Guild about the year 967; and was probably of a much more ancient foundation, for it was the gate through which the Roman Vicinal way lay to the ferry at Oldford. In the time of the wars betwixt king John and his barons, the latter entered the city through this gate, and committed great devastations among the houses of the religious. Aldgate was rebuilt by the leaders of the party after the Roman manner. They made use of stone which they brought from Caen, and a small brick called the *Flanders tile*, which Mr Pennant thinks has been often mistaken for Roman. The new gate was very strong, and had a deep well within it. In 1471 this gate was assaulted by the Bastard of Falconbridge, who got possession of it for a few hours; but the portcullis being drawn up, the troops which had entered were all cut off, and the citizens, headed by the alderman of the ward and recorder, having made a rally, defeated the remainder with great slaughter. In 1606 Aldgate was taken down and rebuilt; and many Roman coins were found in digging the foundations.—The ward of Aldgate is bounded on the east by the city-wall, which divides it from Port-foken-ward; on the north, by Bishopsgate ward; on the west, by Lime-street and Langbourn wards; and on the south, by Tower-street ward. It is governed by an alderman, six common-council men, six constables, N° 186.

twenty inquest-men, seven scavengers, and a beadle; London. besides the officers belonging to St James's, Duke's Place.—It is divided into seven precincts.

3. *Bassishaw* or *Basinghall ward*, is bounded on the east and south by Coleman-street ward, on the north by part of Cripplegate, and on the west by part of the wards of Cheap and Cripplegate. On the south, it begins at Blackwell-hall; and runs northward to London-wall, pulled down some time ago to make way for new buildings in *Foresstreet*, and spreads 88 feet east, and 54 feet west against the place where that wall stood. This is a very small ward, and consists only of two precincts: the upper precinct contains no more than 66, and the lower only 76 houses. It is governed by an alderman, four common-council men, of whom one is the alderman's deputy, three constables, seventeen inquest-men, three scavengers, and a beadle. It has its name from Basinghall, the mansion-house of the family of *Bafin*, which was the principal house in it, and stood in the place of Blackwell-hall.

4. *Billingsgate ward* is bounded on the east by Tower-street ward; on the north, by Langbourn ward; on the west, by the ward of Bridge-within; and on the south, by the river Thames. There have been many conjectures concerning the origin of the name of *Billingsgate*, none of which seems to be very well authenticated. It is, for instance, supposed to have derived its name from a British king named *Belinus*, said to have been an assistant of Brennus king of the Gauls at the taking of Rome, and is the same with the *Bel-Maur* mentioned in the Welsh genealogies. The name of *Ludgate* is said to be derived from his son *Lud*.—It is divided into 12 precincts; and is governed by an alderman, 10 common-council men, one of whom is the alderman's deputy, 11 constables, 14 inquest-men, six scavengers, and a beadle. The situation of Billingsgate, on the river, gives it great advantages with respect to trade and merchandise; so that it is well inhabited, and is in a continual hurry of business at the several wharfs or quays.

5. *Bishopsgate ward* is bounded on the east by Aldgate ward, Portfoken ward, and part of the Tower-liberty, or Norton-falgate; on the west, by Broad-street ward and Moorfields; and on the south, by Langbourn ward. It is very large, and divided into Bishopsgate-within and Bishopsgate-without. The first contains all that part of the ward within the city-wall and gate, and is divided into five precincts; the second lies without the wall, and is divided into four precincts. Bishopsgate-without extends to Shoreditch, taking its name from one Sir John de Sordich, an eminent lawyer much in favour with king Edward III. both on account of his knowledge in the law, and of his personal valour. In the time of Henry VIII. one Barlo, a citizen and inhabitant of this place, was named *duke of Shoreditch*, on account of his skill in archery; and, for a number of years after, the title belonged to the captain of the London archers. This ward is governed by an alderman, two deputies, one within and the other without, 12 common-council men, seven constables, 13 inquest-men, nine scavengers, and two beadles. It took its name from the gate, which has been pulled down to make that part of the city more airy and commodious. This gate was built by

Erkenwald

London. Erkenwald bishop of London in 675; and it is said to have been repaired by William the Conqueror soon after the Norman conquest. In the time of Henry III. the Hanse merchants had certain privileges confirmed to them, in return for which they were to support this gate; and in consequence of this they rebuilt it elegantly in 1479. There were two statues of bishops, in memory of the founder and first repairer; other two were also put up, which are supposed to have been designed for Alfred and Ældred earl of Mercia, to whose care the gate had been committed.

6. *Bread-street ward* is encompassed, on the north and north-west, by the ward of Faringdon-within; on the east, by Cordwainer's ward; on the south by Queen-hite-ward; and on the west, by Castle-Baynard ward. It is divided into 13 precincts; and is governed by an alderman; 12 common-council-men, of whom one is the alderman's deputy, 13 constables, 13 inquest-men, 13 scavengers, and a beadle; and yet contains no more than 331 houses. It takes its name from the ancient bread-market, which was kept in the place now called *Bread-street*; the bakers being obliged to sell their bread only in the open market and not in shops.

7. *Bridge-ward within* is bounded on the south by the river Thames and Southwark; on the north, by Langbourn and Bishopsgate ward; on the east, by Billingsgate; and on the west, by Candlewick and Dowgate wards. It is divided into 14 precincts, three of which were on London-bridge; and is governed by an alderman, 15 common-council men, one of whom is the alderman's deputy, 14 constables, 15 inquest-men, 14 scavengers, and a beadle. It takes its name from its connection with London-bridge.

8. *Broad-street ward* is bounded, on the north and east, by Bishopgate ward; on the south, by Cornhill and Wallbrook ward; and on the west by Coleman-street ward. It is divided into 10 precincts; and governed by an alderman, 10 common-council men, one of whom is the alderman's deputy, 10 constables, 13 inquest-men, eight scavengers, and a beadle. It has its name from that part of it now distinguished by the name of *Old Broad-street*; and which, before the fire of 1666, was accounted one of the broadest streets in London.

9. *Candlewick ward, Candlewick-street, or Candlewright street ward* as it is called in some ancient records, is bounded on the east by Bridge ward; on the south, by Dowgate and part of Bridge ward; on the west, by Dowgate and Wallbrook; and on the north, by Langbourn ward. It is but a small ward, consisting of about 286 houses; yet is divided into seven precincts. It is governed by an alderman, eight common-council men, of whom one is the alderman's deputy, seven constables, 13 inquest-men, seven scavengers, and a beadle. It has its name from a street, formerly inhabited chiefly by candlewrights or candle-makers, both in tallow and wax: a very profitable business in the times of Popery, when incredible quantities of wax-candles were consumed in the churches. That street, however, or at least its name, *Candlewick*, is lost since the great conflagration, for which the name *Canon-street* is substituted, the candlewrights being at that time burnt out and dispersed through the city.

10. *Castle-Baynard ward* is bounded by Queen-

hithe and Bread-street wards on the east; on the south, by the Thames; and on the west and north, by the ward of Faringdon-within. It is divided into 10 precincts, under the government of an alderman, 10 common-council-men, one of whom is the alderman's deputy, nine constables, 14 inquest-men, seven scavengers, and a beadle. It takes its name from a castle built on the bank of a river by one Baynard, a soldier of fortune, who came in with William the Conqueror, and was by that monarch raised to great honours and authority.

11. *Cheap ward* is bounded on the east by Broad-street and Broadbrook wards; on the north, by Coleman-street, Bassishaw, and Cripple-gate; and on the south, by Cordwainer's ward. It is divided into nine precincts; and is governed by an alderman, 12 common-council men, of whom one is the alderman's deputy, 11 constables, 13 inquest-men, nine scavengers, and a beadle. It has its name from the Saxon word *chepe*, which signifies a market, kept in this division of the city, now called *Cheapside*; but then known by the name of *Westeheap*, to distinguish it from the market then also kept in Eastcheap, between Canon or Candlewick street and Tower-street.

12. *Coleman-street ward* is bounded on the east by Bishopgate, Broadstreet, and Cheap wards; on the north, by Cripple-gate ward, Middle Moorfields, and Bishopgate; on the south, by Cheap ward; and on the west, by Bassishaw ward. It is divided into six precincts; and is governed by an alderman, six common-council men, one of whom is the alderman's deputy, six constables, 13 inquest-men, six scavengers, and a beadle. The origin of the name is not certainly known.

13. *Cordwainers ward* is bounded on the east by Wallbrook, on the south by Vintry ward, on the west by Bread-street, and on the north by Cheap-ward. It is divided into eight precincts; and is governed by an alderman, eight common-council men, one of whom is the alderman's deputy, eight constables, 14 inquest men, eight scavengers, and a beadle. Its proper name is *Cordwainers-street ward*; which it has from Cordwainers street, now Bow-lane, formerly occupied chiefly by shoemakers and others that dealt or worked in leather.

14. *Cornhill ward* is but of small extent. It is bounded on the east by Bishopgate, on the north by Broad street, on the west by Cheap ward, and on the south by Langbourn ward. It is divided into four precincts, which are governed by one alderman, six common-council men, of whom one is the alderman's deputy, four constables, 16 inquest-men, four scavengers, and a beadle. It takes its name from the principal street in it, known from the earliest ages by the name of *Cornhill*, because the corn-market was kept there.

15. *Cripple-gate ward* is bounded on the east by Moorfields, Coleman-street ward, Bassishaw ward, and Cheap ward; on the north by the parish of St Luke's, Old-street; on the west, by Alder-gate ward; and on the south, by Cheap-ward. It is divided into 13 precincts, nine within and four without the wall; and is governed by an alderman, 12 common council men, of whom two are the alderman's deputies, 13 constables, 34 inquest-men, 16 scavengers, and three beades. It

London. takes its name from Cripplegate, which stood on the north-west part of the city-wall. It was an old plain structure, void of all ornament, with one postern; but had more the appearance of a fortification than any of the other gates. It was removed in order to widen the entrance into Wood-street, which, by the narrowness of the gateway, was too much contracted and rendered dangerous for passengers and great waggon.

16. *Dowgate ward* is bounded on the east by Candlewick and Bridge wards, on the north by Wallbrook ward, on the west by Vintry ward, and on the south by the Thames. It is divided into eight precincts, under the government of an alderman, eight common-council men, of whom one is the alderman's deputy, eight constables, 15 inquest-men, five scavengers, and a beadle. It has its name from the ancient water-gate, called *Dowgate*, which was made in the original wall that ran along the north side of the Thames, for the security of the city against all attempts to invade it by water.

17. *Farringdon ward within* is bounded on the east by Cheap ward and Baynard-cattleward; on the north, by Aldersgate and Cripplegate wards, and the liberty of St Martin's le Grand; on the west, by Farringdon-without; and on the south, by Baynard-cattle ward, and the river Thames. It is divided into 18 precincts; and governed by one alderman, 17 common-council men, of whom one is the alderman's deputy, 19 constables, 17 inquest-men, 19 scavengers, and two beades. It takes its name from William Farringdon citizen and goldsmith of London, who, in 1279, purchased all the aldermanry with the appurtenances, within the city of London and suburbs of the same, between Ludgate and Newgate, and also *without* these gates.

18. *Farringdon-ward without* is bounded on the east by *Farringdon within*, the precinct of the late priory of St Bartholomew near Smithfield, and the ward of Aldersgate; on the north, by the charter-house, the parish of St John's Clerkenwell, and part of St Andrew's parish without the freedom; on the west, by High Holborn and St Clement's parish in the Strand; and on the South by the river Thames. It is governed by one alderman, 16 common-council men, of whom two are the alderman's deputies, 23 constables, 48 inquest-men; 24 scavengers; and four beades. It takes its name from the same goldsmith who gave name to Farringdon-within.

19. *Langborn ward* is bounded on the east by Aldgate ward; on the north, by part of the same, and Limestreet ward; on the south, by Tower-street, Billingsgate, Bridge, and Candlewick wards; and on the west by Wallbrook. It is divided into 12 precincts. It had its name from a rivulet or long bourn of fresh-water, which anciently flowed from a spring near Magpye alley adjoining to St Catherine Coleman's church.

20. *Limestreet ward* is bounded on the east and north by *Aldgate ward*, on the west by Bishopsgate; and on the south by Langbourn ward. It is divided into four precincts; and governed by an alderman, four common-council men, one of whom is the alderman's deputy, four constables, 13 inquest-men, four scavengers, and a beadle. It is very small; and has its name

from some lime-kilns that were formerly built in or near Lime-street.

21. *Portoken ward* is bounded on the east by the parishes of Spitalfields, Stepney, and St George's in the east; on the south, by Tower-hill; on the north, by Bishopsgate ward, and on the west by Aldgate ward. It is divided into five precincts; and is governed by an alderman, five common-council men, one of whom is the alderman's deputy, five constables, 19 inquest-men, five scavengers, and a beadle. Its name signifies the *franchise of the liberty gate*. This Portoken was for some time a guild; and had its beginning in king Edgar, when 13 knights, "well-beloved of the king and realm, for services by them done," requested to have a certain portion of land on the east part of the city left desolate and forsaken of the inhabitants by reason of too much servitude. They besought the king to have this land, with the liberty of a guild for ever. The king granted their request on the following conditions, *viz.* that each of them should victoriously accomplish three combats, one above the ground, one under ground, and the third in the water: and after this, at a certain day, in East Smithfield, they should run with spears against all comers. All this was gloriously performed; upon which the king named it *Knighten Guild*, and extended it from Aldgate to the places where the bars now are on the east, and to the Thames on the south, and as far into the water as an horseman could ride at low water and throw his spear.

22. *Queen-hithe ward* is bounded on the east by Dowgate, on the north by Bread-street and Cordwainers wards, on the south by the Thames, and on the west by Castle-Baynard ward. It is divided into nine precincts; and is governed by one alderman, six common-council men, one of whom is the alderman's deputy, and nine constables. It has its name from the *hithes*, or harbour for large boats, barges, and lighters; for which, and even for ships, it was the anchoring place, and the key for lading and unloading vessels almost of any burden used in ancient times. It has the name of *queen*, because the queens of England usually possessed the tolls and customs of vessels that unloaded goods at this hithe, which were very considerable.

23. *Tower ward*, or *Tower-street ward*, is bounded on the south by the river Thames, on the east by Tower-hill and Aldgate ward, on the north by Langbourn ward, and on the west by Billingsgate ward. It is governed by one alderman, 12 common-council men, of whom one is the alderman's deputy, 12 constables, 13 inquest men, 12 scavengers, and one beadle. It takes its name from *Tower-street*, so called because it leads out of the city in a direct line to the principal entrance of the Tower of London.

24. *Vintry ward* is bounded on the east by Dowgate, on the south by the Thames, on the west by Queen-hithe ward, and on the north by Cordwainers ward. It is a small ward, containing only 418 houses; but is divided into nine precincts, and governed by an alderman, nine common-council men, one of whom is the alderman's deputy, nine constables, 13 inquest-men, three scavengers, and a beadle. It takes its name from the vintners or wine-merchants of Bourdeaux, who formerly dwelt in this part of the city, were obliged to land their wines on this spot, and to sell them in 40 days, till the 28th of Edward I.

London.

25. *Wallbrook ward* is bounded on the east by Lambourn, on the south by Dowgate ward, on the west by Cordwainers ward, and on the north by Cheap ward. It is small, containing only 306 houses; but is divided into seven precincts, and governed by an alderman, eight common-council men, of whom one is the alderman's deputy, seven constables, 13 inquest-men, six scavengers, and a beadle. It has its name from the rivulet *Wallbrook*, that ran down the street of this name into the river Thames near Dowgate; but in process of time it was so lost by covering it with bridges and buildings upon those bridges, that its channel became a common sewer.

26. The ward of *Bridge-without* includes the borough of Southwark, and the parishes of Rotherhithe, Newington, and Lambeth. It has its name from London-bridge, with the addition of the word *without*, because the bridge must be passed in order to come at it. *Westminster* is generally reckoned a part of London, tho' under a distinct government; and has long been famous for the palaces of our kings, the seat of our law tribunals, and of the high court of parliament; all which shall be described in their order.

The city and liberties of London are under an ecclesiastical, a civil, and a military government.

As to its *ecclesiastical* government, London is a bishop's see, the diocese of which comprehends not only Middlesex, Essex, and part of Hertfordshire, but the British plantations in America. The bishop of London takes precedence next to the archbishops of Canterbury and York; but the following parishes of this city are exempt from his jurisdiction, being peculiars under the immediate government of the archbishop of Canterbury; *viz.* All-hallows in Bread-street, All-hallows Lombard-street; St Dionys Back-church, St Dunstan in the East, St John Baptist, St Leonard Eastcheap, St Mary Aldermay, St Mary Bothaw, St Mary le Bow, St Michael Crooked-lane, St Michael Royal, St Pancras Soper-lane, and St Vedast Foster-lane.

The *civil* government of London divides it into wards and precincts, under a lord-mayor, aldermen, and common-council.

The mayor, or lord-mayor, is the supreme magistrate, chosen annually by the citizens, pursuant to a charter of King John. The present manner of electing a lord-mayor is by the liverymen of the several companies, assembled in Guildhall annually on Michaelmas-day, according to an act of common council in A. D. 1476, where, and when, the liverymen choose, or rather nominate, two aldermen below the chair, who have served the office of sheriff, to be returned to the court of aldermen, who may choose either of the two; but generally declare the senior of the two, to be returned, to be lord-mayor elect. The election being over, the lord-mayor elect, accompanied by the recorder and divers aldermen, is soon after presented to the lord-chancellor (as his majesty's representative in the city of London) for his approbation; and on the 9th of November following is sworn into the office of mayor at Guildhall; and on the day after, before the barons of the exchequer at Westminster; the procession on which occasion is exceedingly grand and magnificent.

The lord-mayor sits every morning at the mansion-house, or place where he keeps his mayoralty, to de-

termine any difference that may happen among the citizens, and to do other business incident to the office of a chief magistrate. Once in six weeks, or eight times in the year, he sits as chief judge of Oyer and Terminer, or gaol-delivery of Newgate for London and the county of Middlesex. His jurisdiction extends all over the city and suburbs, except some places that are exempt. It extends also from Colneyditch, above Staines-bridge in the west, to Yeudale, or Yensflete, and the mouth of the river Medway, and up that river to Upnor-castle, in the east; by which he exercises the power of punishing or correcting all persons that shall annoy the streams, banks, or fish. For which purpose his lordship holds several courts of conservancy in the counties adjacent to the said river, for its conservation, and for the punishment of offenders. See the article *MAYOR'S-COURT*.

The title of dignity, *alderman*, is of Saxon original, and of the greatest honour, answering to that of earl; though now it is nowhere to be found but in chartered societies. And from hence we may account for the reason why the aldermen and commonalty of London were called *barons* after the conquest. These magistrates are properly the subordinate governors of their respective wards under the lord-mayor's jurisdiction; and they originally held their aldermanries either by inheritance or purchase; at which time the aldermanries or wards changed their names as often as their governors or aldermen. The oppressions, to which the citizens were subject from such a government, put them upon means to abolish the perpetuity of that office; and they brought it to an annual election. But that manner of election being attended with many inconveniences, and becoming a continual bone of contention amongst the citizens, the parliament, 17 Richard II. A. D. 1394, enacted, That the aldermen of London should continue in their several offices during life or good behaviour. And so it still continues: though the manner of electing has several times varied. At present it is regulated by an act of parliament, passed in the year 1724-5: and the person so elected is to be returned by the lord-mayor (or other returning officer in his stead, duly qualified to hold a court of wardmote) to the court of lord-mayor and aldermen, by whom the person so returned must be admitted and sworn into the office of alderman before he can act. If the person chosen refuse to serve the office of alderman, he is finable 500 l.

These high officers constitute a second part of the city legislature when assembled in a corporate capacity, and exercise an executive power in their respective wards. The aldermen who have passed the chair, or served the high office of lord-mayor, are justices of the quorum; and all the other aldermen are not only justices of the peace, but by the statute of 43 Eliz. intitled, *An act for the relief of the poor*, "every alderman of the city of London, within his ward, shall and may do and execute, in every respect, so much as is appointed and allowed by the said act to be done or executed by one or two justices of peace of any county within this realm." They every one keep their *wardmote*, or court, for choosing ward-officers and settling the affairs of the ward, to redress grievances, and to prevent all defaults found within their respective wards.

The next branch of the legislative power in this city

London.

36
Common-council.

city is the *common-council*. The many inconveniences that attended popular assemblies, which were called *folk-motes*, determined the commonality of London to choose representatives to act in their name and for their interest, with the lord-mayor and aldermen, in all affairs relating to the city. At first these representatives were chosen out of the several companies: but that not being found satisfactory, nor properly the representatives of the whole body of the inhabitants, it was agreed to choose a certain number of discreet men out of each ward: which number has from time to time increased according to the dimensions of each ward: and at present the 25 wards, into which London is divided, being subdivided into 236 precincts, each precinct sends a representative to the common-council, who are elected after the same manner as an alderman, only with this difference, that as the lord-mayor presides in the wardmote, and is judge of the poll at the election of an alderman, so the alderman of each ward is judge of the poll at the election of a common-council man.

Thus the lord-mayor, aldermen, and common-council, when assembled, may be deemed the city parliament, resembling the great council of the nation. For it consists of two houses; one for the lord-mayor and aldermen, or the upper-house; another for the commoners or representatives of the people, commonly called the *common-council men*. And they have power in their incorporate capacity to make and repeal by-laws; and the citizens are bound to obey or submit to those laws. When they meet in their incorporate capacity, they wear deep-blue silk gowns: and their assemblies are called the *court of common-council*, and their ordinances *acts of common-council*. No act can be performed in the name of the city of London without their concurrence. But they cannot assemble without a summons from the lord-mayor; who, nevertheless, is obliged to call a common-council, whenever it shall be demanded, upon extraordinary occasions, by six reputable citizens and members of that court.

37
Sheriffs.

This corporation is assisted by two sheriffs and a recorder. The sheriffs are chartered officers, to perform certain suits and services, in the king's name, within the city of London and county of Middlesex, chosen by the liverymen of the several companies on Midsummer day. Their office, according to Camden, in general, is to collect the public revenues within their several jurisdictions; to gather into the exchequer all fines belonging to the crown; to serve the king's writs of process; to attend the judges, and execute their orders; to impanel juries; to compel headstrong and obstinate men by the *posse comitatus* to submit to the decisions of the law; and to take care that all condemned criminals be duly punished and executed. In particular, in London, they are to execute the orders of the common-council, when they have resolved to address his majesty, or to petition parliament.

The sheriffs, by virtue of their office, hold a court at Guildhall every Wednesday and Friday, for actions entered at Wood-fleet Compter; and on Thursdays, and Saturdays for those entered at the Poultry Compter: of which the sheriffs being judges, each has his assistant, or deputy, who are called the judges of those courts; before whom are tried actions of debt, trespass, covenant, &c. and where the testimony of any

able witness in writing is allowed to be good evidence. To each of these courts belong four attorneys, who, upon their being admitted by the court of auditors, have an oath administered to them.

To each of these courts likewise belong a secondary, a clerk of the papers, a prothonotary, and four clerks-fitters. The secondary's office is to allow and return all writs brought to remove clerks out of the said courts; the clerk of the papers files and copies all declarations upon actions; the prothonotary draws and ingrosses all declarations; the clerk-fitters enter actions and attachments, and take bail and verdicts. To each of the compters, or prisons belonging to these courts, appertain 16 sergeants at mace, with a yeoman to each, besides inferior officers, and the prison-keeper.

In the sheriffs court may be tried actions of debt, case, trespass, account, covenant, and all personal actions, attachments, and sequestrations. When an erroneous judgment is given in either of the sheriffs courts of the city, the writ of error to reverse this judgment must be brought in the court of hustings before the lord mayor; for that is the superior court. The sheriffs of London may make arrests and serve executions on the river Thames.

38
Recorder.

We do not read of a recorder till the 1304, who, by the nature of his office, seems to have been intended as an assistant to, or assessor with, the lord-mayor, in the execution of his high office, in matters of justice and law. He is chosen by the lord-mayor and aldermen only; and takes place in all courts, and in the common-council, before any one that hath not been mayor. Of whom we have the following description in one of the books of the chamber. "He shall be, and is wont to be, one of the most skilful and virtuous apprentices of the law of the whole kingdom; whose office is always to sit on the right hand of the mayor, in recording pleas, and passing judgments; and by whom records and processess, had before the lord-mayor and aldermen at Great St Martin's, ought to be recorded by word of mouth before the judges assigned there to correct errors. The mayor and aldermen have therefore used commonly to set forth all other business, touching the city, before the king and his council, as also in certain of the king's courts, by Mr Recorder, as a chief man, endowed with wisdom, and eminent for eloquence."—Mr Recorder is looked upon to be the mouth of the city, to deliver all addresses to the king, &c. from the corporation; and he is the first officer in order of precedence that is paid a salary, which originally was no more than 10*l*. Sterling *per annum*, with some few perquisites; but it has from time to time been augmented to 1000*l*. *per annum*, and become the road to preferment in the law. This office has sometimes been executed by a deputy.

The next chartered officer of this corporation is the chamberlain; an office of great repute and trust, and is in the choice of the livery annually. This officer, though chosen annually on Midsummer-day, is never displaced during his life, except some very great crime can be made out against him. He has the keeping of the moneys, lands, and goods, of the city-orphans, or takes good security for the payment thereof when the parties come to age. And to that end he is deemed in the law a sole corporation, to him and his successors.

39
Chamberlain.

London. fors, for orphans; and therefore a bond or a recognition made to him and his successors, is recoverable by his successors. This officer hath a court peculiarly belonging to him. His office may be termed a public treasury, collecting the customs, moneys, and yearly revenues, and all other payments belonging to the corporation of the city. It was customary for government to appoint the chamberlain receiver of the land tax; but this has been discontinued for several years past.

40
Other of-
ficers.

The other officers under the lord-mayor are, 1. The common serjeant. He is to attend the lord-mayor and court of aldermen on court-days, and to be in council with them on all occasions, within or without the precincts or liberties of the city. He is to take care of orphans estates, either by taking account of them, or to sign their indentures, before their passing the lord-mayor and court of aldermen. And likewise he is to let, set, and manage the orphans estates, according to his judgment, to the best advantage. 2. The town-clerk; who keeps the original charter of the city, the books, rolls, and other records, wherein are registered the acts and proceedings of the city; so that he may not be improperly termed the city-register: he is to attend the lord-mayor and aldermen at their courts, and signs all public instruments. 3. The city-remembrancer; who is to attend the lord-mayor on certain days, his business being to put his lordship in mind of the feoff days he is to go abroad with the aldermen, &c. He is to attend daily at the parliament-house, during the sessions, and to report to the lord-mayor their transactions. 4. The sword-bearer; who is to attend the lord-mayor at his going abroad, and to carry the sword before him, being the emblem of justice. This is an ancient and honourable office, representing the state and princely office of the king's most excellent majesty, in his representative the lord-mayor; and, according to the rule of armory, "He must carry the sword upright, the hilts being holden under his bulk, and the blade directly up the middle of his breast, and so forth between the sword-bearer's brows." 5. The common-hunt; whose business it is to take care of the pack of hounds belonging to the lord-mayor and citizens, and to attend them in hunting in those grounds to which they are authorized by charter. 6. The common-crier. It belongs to him and the serjeant at arms, to summon all executors and administrators of freemen to appear, and to bring in inventories of the personal estates of freemen, within two months after their decease: and he is to have notice of the appraisements. He is also to attend the lord-mayor on set days, and at the courts held weekly by the mayor and aldermen. 7. The water-bailiff; whose office is to look after the preservation of the river Thames against all encroachments; and to look after the fishermen for the preservation of the young fry, to prevent the destroying them by unlawful nets. For that end, there are juries for each county, that hath any part of it lying on the sides or shores of the said river; which juries, summoned by the water-bailiff at certain times, do make inquiry of all offences relating to the river and the fish, and make their presentments accordingly. He is also bound to attend the lord-mayor on set days in the week.—These seven purchase their places; except the town-clerk, who is chosen by the livery.

There are also three serjeant-carvers; three serjeants

of the chamber; a serjeant of the channel: four yeomen of the water-side; an under water-bailiff; two yeomen of the chamber; two meal-weighters; two yeomen of the wood wharfs; a foreign taker; city-marshals. There are besides these, seven gentlemen men; as, the sword-bearer's man, the common-hunt's two men, the common crier's man, and the carver's three men.

Nine of the foregoing officers have liveries of the lord-mayor, viz. the sword-bearer and his man, the three carvers, and the four yeomen of the water-side. All the rest have liveries from the chamber of London.

The following officers are likewise belonging to the city; farmer of the markets, auditor, clerk of the chamber, clerk to the commissioners of the sewers, clerk of the court of conscience, beadle of the same court, clerk of the city-works, printer to the city, justice of the Bridge-yard, clerk-comptroller of the Bridge-house, steward of the Borough, bailiff of the Borough.

There is also a coroner, called so from *corona*, i. e. a crown, because he deals principally with the crown, or in matters appertaining to the imperial crown of England. See the article CORONER.

Besides these officers, there are several courts in this city for the executing of justice, viz. the court of hustings, lord-mayor's court, &c. In the city there are also two subordinate kinds of government. One executed by the alderman, deputy, and common-council men, and their inferior officers, in each ward; under which form are comprehended all the inhabitants, free or not free of the city. Every ward is therefore like a little free state, and at the same time subject to the lord-mayor as chief magistrate of the city. The housekeepers of each ward elect their representatives, the common-council, who join in making bye-laws for the government of the city. The officers and servants of each ward manage the affairs belonging to it, without the assistance of the rest; and each has a court called the *wardmote*, as has been already described, for the management of its own affairs. The other, by the master, wardens, and court of assistants, of the incorporate companies; whose power reaches no further than over the members of their respective guilds or fraternities; except that in them is invested the power to choose representatives in parliament for the city; and all those magistrates and officers elected by a common-hall; which companies are invested with distinct powers, according to the tenor of their respective charters.

The military government of the city is lodged in a Military lieutenantancy, consisting of the lord-mayor, aldermen, and other principal citizens, who receive their authority by a commission from the king. Those have under their command the city trained bands, consisting of six regiments of foot, distinguished by the names of the *white, orange, yellow, blue, green, and red*, each containing eight companies of 150 men, amounting in all to 7200. Besides these six regiments, there is a corps called the *artillery company*, from its being taught the military exercise in the artillery-ground. This company is independent of the rest, and consists of 700 or 800 volunteers. All these, with two regiments of foot of 800 men each commanded by the lieutenant of the Tower of London, make the whole militia of this city; which,

which, exclusive of Westminster and the borough of Southwark, amounts to about 10,000 men.

43
Trading
companies.

The trading part of the city of London is divided into 89 companies; though some of them can hardly be called so, because they have neither charters, halls, nor livery. Of these 89 companies 55 have each a hall for transacting the business of the corporation; and this consists of a master or prime warden, a court of assistants, and livery.—Twelve of these companies are superior to the rest both in antiquity and wealth; and of one of those 12 the lord mayors have generally made themselves free at their election. These companies are the mercers, grocers, drapers, fish-mongers, goldsmiths, skinner, merchant-tailors, haberdashers, salters, iron-mongers, vintners, and clothworkers.—The principal incorporated societies of the merchants of this city are, the *Hamburgh Company*, the *Hudson's Bay Company*, the *Russia Company*, the *Turkey Company*, the *East India Company*, the *Royal African Company*, the *South Sea Company*, and some *Insurance Companies*. The most of these companies have stately houses for transacting their business, particularly the *East India* and *South Sea companies*. See *COMPANY*.

The streets and public buildings in London and its liberties being far too numerous for a particular description in this work, we shall only select the most remarkable, beginning with *London-Bridge* as the most ancient, and proceeding in our survey through the wards into which the city is divided.

43
Remarkable streets
and buildings
within
the
City.

1. *Remarkable buildings, &c. in the City*.—The original bridge, which stands in Bridge-ward, was of wood, and appears to have been first built between the years 993 and 1016; but being burnt down about the year 1130, it was rebuilt of wood in 1163. The expenses, however, of maintaining and repairing it became so burdensome to the inhabitants of the city, that they resolved to build a stone-bridge a little westward of the wooden one. This building was begun in 1176, and finished in 1209; and was 915 feet long, 44 feet high, and 73 feet wide; but houses being built on each side, the space between was only 23 feet.

44
London
bridge.

This great work was founded on enormous piles driven as closely as possible together: on their tops were laid long planks 10 inches thick, strongly bolted; and on them were placed the base of the pier, the lowermost stones of which were bedded in pitch, to prevent the water from damaging the work: round all were the piles which were called the *sterlings*, designed for the preservation of the foundation piles. These contracted the space between the piers so greatly, as to occasion at the retreat of every tide a fall of five feet, or a number of temporary cataracts, which

since the foundation of the bridge have occasioned the loss of many thousand lives. The number of arches was 19, of unequal dimensions, and greatly deformed by the *sterlings* and the houses on each side, which overhung and leaned in a most terrific manner. In most places they hid the arches, and nothing appeared but the rude piers. Within recollection, frequent arches of strong timber crossed the street from the tops of the houses to keep them together, and from falling into the river (A). Nothing but use could preserve the quiet of the inmates, who soon grew deaf to the noise of the falling waters, the clamours of watermen, or the frequent shrieks of drowning wretches. In one part had been a drawbridge, useful either by way of defence or for the admission of ships into the upper part of the river. This was protected by a strong tower. It served to repulse *Fauconbridge* the *Barbador* in his general assault on the city in 1471, with a set of banditti, under pretence of rescuing the unfortunate *Henry*, then confined in the Tower. Sixty houses were burnt on the bridge on the occasion. It also served to check, and in the end annihilate, the ill-conducted insurrection of *Sir Thomas Wyatt*, in the reign of *Queen Mary*. The top of this tower, in the sad and turbulent days of this kingdom, used to be the shambles of human flesh, and covered with heads or quarters of unfortunate partizans. Even so late as the year 1598, *Hentzner*, the German traveller, with German accuracy, counted on it above 30 heads. The old map of the city in 1597 represents them in a most horrible cluster.—An unparalleled calamity happened on this bridge within four years after it was finished. A fire began on it at the Southward end; multitudes of people rushed out of London to extinguish it, while they were engaged in this charitable design, the fire seized on the opposite end, and hemmed in the crowd. Above 3000 persons perished in the flames, or were drowned by overloading the vessels which were hardly enough to attempt their relief.

The narrowness of the passage on this bridge having occasioned the loss of many lives from the number of carriages continually passing; and the straitness of the arches, with the enormous size of the *sterlings*, which occupied one-fourth part of the water-way, having also occasioned frequent and fatal accidents, as already mentioned; the magistrates of London in 1756 obtained an act of parliament for improving and widening the passage over and through the bridge, which granted them a toll for every carriage and horse passing over it, and for every vessel with goods passing through it: but these tolls proving insufficient, were abolished by an act made in 1758 for explaining, amending, and rendering the former act more effectual; and for granting the city of London money towards carrying on that

London.

(A) The gallant action of *Edmund Osborne*, ancestor to the duke of Leeds, when he was apprentice to *Sir William Hewet* cloth-worker, may not improperly be mentioned in this place. About the year 1536, when his master lived in one of those tremendous houses, a servant-maid was playing with his only daughter in her arms in a window over the water, and accidentally dropt the child. Young *Osborne*, who was witness to the misfortune, instantly sprang into the river, and, beyond all expectation, brought her safe to the terrified family! Several persons of rank paid their addresses to her when she was marriageable, among others the earl of *Shrewsbury*; but *Sir William* gratefully decided in favour of *Osborne*: *Osborne*, says he, saved her, and *Osborne* shall enjoy her. In her right he possessed a great fortune. He became sheriff of London in 1575, and lord-mayor in 1582.

London. that work. In consequence of these acts of parliament, a temporary wooden bridge was built, and the houses on the old bridge were taken down. Instead of a narrow street 23 feet wide, there is now a passage of 31 feet for carriages, with a raised pavement of stone on each side 7 feet broad for the use of foot passengers. The fides are secured by stone balustrades, enlightened in the night with lamps. "The passage thro' the bridge is enlarged by throwing the two middle arches into one, and by other alterations and improvements; notwithstanding which, however, it is still greatly subject to its former inconveniences.—Under the first, second, and fourth arches, from the north side of the bridge, and now likewise towards the southern extremity, there are engines worked by the flux and reflux of the river, the water of which they raise to such a height as to supply many parts of the city. Those engines were contrived in 1582 by one Peter Morice a Dutchman, and are called *London-bridge water works*.

48
The Monument.

Near the north side of London bridge stands the *Monument*, a beautiful and magnificent fluted column of the Doric order, built with Portland stone, and erected in memory of the conflagration 1666. It was begun by Sir Christopher Wren in 1671, and finished by him in 1677. Its height from the pavement is 202 feet; the diameter of the shaft, or body of the column, is 15 feet; the ground-plinth, or lowest part of the pedestal, is 28 feet square; and the pedestal is 40 feet high. Over the capital is an iron balcony encompassing a cone 32 feet high, which supports a blazing urn of gilt brass. Within is a large staircase of black marble, containing 345 steps, each 10 inches and a half broad, and six inches thick. The west side is adorned with a curious emblem in alt-relief, denoting the destruction and restoration of the city. The first female figure represents London sitting in ruins, in a languishing posture, with her head dejected, her hair dishevelled, and her hand carelessly lying on her sword. Behind is *Time*, gradually raising her up: at her side is a woman touching her with one hand, whilst a winged sceptre in the other directs her to regard the goddesses in the clouds; one with a cornucopia, denoting *Plenty*; the other with the palm branch, the emblem of *Peace*. At her feet is a bee-hive, showing, that by industry and application the greatest misfortunes are to be overcome. Behind the figure of *Time* are citizens exulting at his endeavours to restore her; and beneath, in the midst of the ruins, is a dragon, who, as the supporter of the city arms, with his paw endeavours to preserve the same. Opposite to the city, on an elevated pavement, stands the king, in a Roman habit, with a laurel on his head, and a truncheon in his hand; and approaching her, commands three of his attendants to defend to her relief. The first represents the *Sciences* with a winged head and circle of naked boys dancing thereon; and holding *Nature* in her hand, with her numerous breasts, ready to give assistance to all. The second is *Architecture*, with a plan in one hand, and square and a pair of compasses in the other; and the third is *Liberty*, waving a hat in the air, showing her joy at the pleasing prospect of the city's speedy recovery. Behind the king stands his brother the duke of York, with a garland in one hand to crown the rising city, and a sword in the other for

her defence. The two figures behind are *Justice* and *Fortitude*; the former with a coronet, and the latter with a reined lion; and under the royal pavement lies *Envy*, gnawing a heart, and incessantly emitting pestiferous fumes from her mouth. On the plinth the reconstruction of the city is represented by builders and labourers at work upon houses. On the north, south, and east sides, are inscriptions relating to the destruction occasioned by the conflagration, the regulations about rebuilding the city, and erecting the monument; and round it is the following one:—"This pillar was set up in perpetual remembrance of the most dreadful burning of this Protestant city, begun and carried on by the treachery and malice of the Popish faction, in the beginning of September, in the year of our Lord 1666, in order to their carrying on their horrid plot for extirpating the Protestant religion and old English liberty, and introducing Popery and slavery." Dr Wendeborn, in his account of London, observes, that the monument, though not much above 100 years old, bears visible marks of decay already; and it will not probably be long before it must be pulled down. Some are of opinion that this is occasioned by the fault of the architect, others by the continual shaking of the ground by coaches; but the Doctor inclines to the latter opinion.

Eastward of the bridge and monument stands the *White Tower*, which gives name to another ward. It is the chief fortress of the city, and supposed to have been originally built by William the Conqueror. It appears, however, to have been raised upon the remains of a more ancient fortress, erected probably by the Romans: for in 1720, in digging on the south side of what is called *Cesar's Chapel*, there were discovered some old foundations of stone, three yards broad, and so strongly cemented that it was with the utmost difficulty they were forced up. The first work (according to Mr Pennant) seems to have been suddenly flung up in 1066 by the Conqueror, on his taking possession of the capital; and included in it a part of the ancient wall.

The great square tower, called the *White Tower*, was erected in the year 1078, when it arose under the directions of Gundulph bishop of Rochester, who was a great military architect. This building originally stood by itself. Fitzstephen gives it the name of *Arx Palatina*, "the Palatine Tower;" the commander of which had the title of Palatine bestowed on him. Within this tower is a very ancient chapel for the use of such of our kings and queens who wished to pay their devotion here. In 1092 a violent tempest did great injury to the Tower; but it was repaired by William Rufus and his successor. The first added another castellated building on the south side between it and the Thames, which was afterwards called *St Thomas's Tower*.

The Tower was first inclosed by William Longchamp, bishop of Ely and chancellor of England, in the reign of Richard I. This haughty prelate having a quarrel with John, third brother to Richard, under pretence of guarding against his designs, surrounded the whole with walls embattled, and made on the outside a vast ditch, into which, in after times, the water from the Thames was introduced. Different princes added other works. The present contents within the walls

London.

London.

walls are 12 acres and 5 rods, the circuit on the outside of the ditch 10½ feet. It was again inclosed with a mud-wall by Henry III. this was placed at a distance from the ditch, and occasioned the taking down part of the city-wall, which was refented by the citizens; who, pulling down this precinct of mud, were punished by the king with a fine of a thousand marks.

The *Lions Tower* was built by Edward IV. it was originally called the *Bulwark*, but received the former name from its use. A menagery had very long been a piece of regal state: Henry I. had his at his manor of Woodstock, where he kept lions, leopards, lynxes, porcupines, and several other uncommon beasts. They were afterwards removed to the Tower. Edward II. commanded the sheriffs of London to pay the keepers of the king's leopards sixpence a day for the sustenance of the leopards, and three halfpence a day for the diet of the keeper out of the fee-farm of the city. The royal menagery is to this day exceedingly well supplied.

In 1758 the Tower-ditch was railed all round. New barracks were some years ago erected on the Tower-wharf, which parts it from the river; and upon the wharf is a line of 61 pieces of cannon, which are fired upon state holidays. On this side of the Tower the ditch is narrow, and over it is a draw-bridge. Parallel to the wharf, within the walls, is a platform 70 yards in length, called the *Ladies Line*, because much fre-

quented by the ladies in the summer; it being shaded in the inside with a row of lofty trees, and without it is a delightful prospect of the shipping with boats passing and repassing on the river Thames. You ascend this line by stone steps, and being once upon it you may walk almost round the walls of the Tower without interruption.

The principal entrance into the Tower is by a gate to the west, large enough to admit coaches and heavy carriages; but these are first admitted through an outward gate, situated without the ditch upon the hill, and must pass a stout stone-bridge built over the ditch before they can approach the main entrance. There is, besides, an entrance near the very south-west corner of the Tower outward wall, for persons on foot, over the draw-bridge already mentioned to the wharf. There is also a water-gate, commonly called *Traitor's gate*, through which it has been customary to convey traitors and other state-prisoners to or from the Tower, and which is seldom opened on any other occasion; but the lords committed to the Tower in 1746 were publicly admitted at the main entrance. Over this gate is a regular building, terminated at each end by two round towers, on which are embrasures for pointing cannon. In this building there are the infirmary, the mill, and the water-works that supply the Tower with water.

In the Tower (the curiosities of which are more particularly described in the note (a), are a church, the

(a) In examining the curiosities of the Tower of London, it will be proper to begin with those on the outside of the principal gate. The first thing a stranger usually goes to visit is the wild beasts; which, from their situation, first present themselves: for having entered the outer gate, and passed what is called the spur-guard, the keeper's house presents itself before you, which is known by a painted lion on the wall, and another over the door which leads to their dens. By ringing a bell, and paying sixpence each person, you may easily gain admittance.

The next place worthy of observation is the Mint, which comprehends near one-third of the Tower, and contains houses for all the officers belonging to the coinage. On passing the principal gate you see the White Tower, built by William the Conqueror. This is a large, square, irregular stone building, situated almost in the centre, no one side answering to another, nor any of its watch-towers, of which there are four at the top, built alike. One of these towers is now converted into an observatory. In the first story are two noble rooms, one of which is a small armoury for the sea-service, it having various sorts of arms, very curiously laid up, for above 10,000 seamen. In the other room are many closets and presses, all filled with warlike engines and instruments of death. Over this are two other floors, one principally filled with arms; the other with arms and other warlike instruments, as spades, shovels, pick-axes, and chevaux de frize. In the upper story are kept match, sheep-skins, tanned hides, &c. and in a little room called Julius Cæsar's chapel, are deposited some records, containing perhaps the ancient usages and customs of the place. In this building are also preserved the models of the new-invented engines of destruction that have from time to time been presented to the government. Near the south-west angle of the White Tower is the Spanish armoury, in which are deposited the spoils of what was vainly called the Invincible Armada; in order to perpetuate to latest posterity the memory of that signal victory obtained by the English over the whole naval power of Spain in the reign of Philip II.

You are now come to the grand store-house, a noble building to the northward of the White Tower, that extends 245 feet in length and 60 in breadth. It was begun by king James II. who built it to the first floor; but it was finished by king William III. who erected that magnificent room called the New or Small Armoury, in which that prince, with queen Mary his consort, dined in great form, having all the warrant workmen and labourers to attend them, dressed in white gloves and aprons, the usual badges of the order of masonry. To this noble room you are led by a folding door, adjoining to the east end of the Tower chapel, which leads to a grand stair-case of 50 easy steps. On the left side of the uppermost landing-place is the work-shop, in which are constantly employed about 14 furnishers, in cleaning, repairing, and new-placing the arms. On entering the armoury, you see what they call a wilderness of arms, so artfully disposed, that at one view you behold arms for near 80,000 men, all bright, and fit for service; a sight which it is impossible to behold without astonishment; and beside those exposed to view, there were, before the late war, 16 chests

London. the offices of ordnance and of the mint, those of the keepers of the records, of the jewel-office, of the Spanish armoury, the horse armoury, and the new or small armoury; with barracks for the soldiers of the garrison, and handsome houses for several officers who reside here. The principal officers of the Tower are,
Vol. X. Part I.

a constable, a lieutenant, and a deputy-lieutenant. Besides London. the longing to this fortress are eleven hamlets; the militia of which, consisting of 400 men, are obliged, at the command of the constable of the Tower, to repair hither, and reinforce the garrison.

On Little Tower-hill is the *Vidualling-office* for the ⁴⁷ Vidualling navy. Office.

shut up, each chest holding about 1000 muskets. The arms were originally disposed by Mr Harris, who contrived to place them in this beautiful order, both here and in the guard chamber of Hampton-court. He was a common gunsmith; but after he had performed this work, which is the admiration of people of all nations, he was allowed a pension from the crown for his ingenuity.

Upon the ground floor, under the small armoury, is a large room of equal dimensions with that, supported by 20 pillars, all hung round with implements of war. This room, which is 24 feet high, has a passage in the middle 16 feet wide. At the sight of such a variety of the most dreadful engines of destruction, before whose thunder the most superb edifices, the noblest works of art, and numbers of the human species, fall together in one common and undistinguished ruin; one cannot help wishing that those horrible inventions had still lain, like a false conception, in the womb of nature, never to have been ripened into birth.

The horse armoury is a plain brick-building, a little to the eastward of the White Tower; and is an edifice rather convenient than elegant, where the spectator is entertained with a representation of those kings and heroes of our own nation, with whose gallant actions it is to be supposed he is well acquainted; some of them equipped and sitting on horseback, in the same bright and shining armour they were used to wear when they performed those glorious actions which gave them a distinguished place in the British annals.

You now come to the line of kings, which your conductor begins by reverting the order of chronology; so that in following them we must place the last first.

In a dark, strong stone room, about 20 yards to the eastward of the grand storehouse, or new armoury, the crown jewels are deposited. 1. The imperial crown, with which it is pretended that all the kings of England have been crowned since Edward the Confessor in 1042. It is of gold, enriched with diamonds, rubies, emeralds, sapphires, and pearls: the cap within is of purple velvet, lined with white taffety, turned up with three rows of ermine. They are, however, mistaken in showing this as the ancient imperial diadem of St Edward: for that, with the other most ancient regalia of this kingdom, was kept in the arched room in the cloisters in Westminster Abbey till the civil war; when, in 1642, Harry Martin, by order of the parliament, broke open the iron chest in which it was secured, took it thence, and sold it, together with the robes, sword, and sceptre, of St Edward. However, after the Restoration, king Charles II. had one made in imitation of it, which is that now shown. 2. The golden orb, or globe, put into the king's right hand before he is crowned; and borne in his left hand, with the sceptre in his right, upon his return into Westminster-hall after he is crowned. It is about six inches in diameter, edged with pearl, and enriched with precious stones. On the top is an amethyst, of a violet colour, near an inch and an half in height, set with a rich cross of gold, adorned with diamonds, pearls, and precious stones. The whole height of the ball and cup is 11 inches. 3. The golden sceptre, with its cross set upon a large amethyst of great value, garnished round with table diamonds. The handle of the sceptre is plain, but the pommel is set round with rubies, emeralds, and small diamonds. The top rises into a *fleur de lis* of six leaves, all enriched with precious stones, from whence issues a mound or ball, made of the amethyst already mentioned. The cross is quite covered with precious stones. 4. The sceptre, with the dove, the emblem of peace, perched on the top of a small Jerusalem cross, finely ornamented with table diamonds and jewels of great value. This emblem was first used by Edward the Confessor, as appears by his seal; but the ancient sceptre and dove was sold with the rest of the regalia, and this now in the Tower was made after the Restoration. 5. St Edward's staff, four feet seven inches and an half in length, and three inches three quarters in circumference, all of beaten gold, which is carried before the king at his coronation. 6. The rich crown of state, worn by his majesty in parliament; in which is a large emerald seven inches round; a pearl esteemed the finest in the world; and a ruby of inestimable value. 7. The crown belonging to his royal highness the prince of Wales. The king wears his crown on his head when he sits upon the throne; but that of the prince of Wales is placed before him, to show that he is not yet come to it. 8. The late queen Mary's crown, globe, and sceptre, with the diadem she wore at her coronation with her consort king William III. 9. An ivory sceptre, with a dove on the top, made for king James II.'s queen, whose garniture is gold, and the dove on the top gold enamelled with white. 10. The *curtana*, or sword of mercy, which has a blade of 32 inches long, and near two broad, is without a point, and is borne naked before the king at his coronation, between the two swords of justice, spiritual and temporal. 11. The golden spurs, and the armillas, which are bracelets for the wrists. These, though very antique, are worn at the coronation. 12. The *empulla*, or eagle of gold, finely engraved, which holds the holy oil the kings and queens of England are anointed with; and the golden spoon that the bishop pours the oil into. These are two pieces of great antiquity. The golden eagle, including the pedestal, is about nine inches high, and the wings expand about seven inches. The whole weighs about ten ounces. The head of the eagle screws off about the middle of the neck, which is made hollow, for holding the holy oil; and when the king is anointed by the bishop, the oil is poured into the spoon out of the bird's bill. 13. A rich

selfseller

London.

navy. It is separated from Tower-hill by a wall and gate, and contains houses for the officers, slaughter-houses, store-rooms, a brew-house, a salting-house, and a barrelling-house; under the direction of seven commissioners and other inferior officers.

48
Custom-house.

In Tower ward is also the *Custom house*, a large, handsome, and commodious building of brick and stone. It stands upon the bank of the Thames, and is accommodated with large wharfs, keys, and ware-houses. On this spot is the busy concourse of all nations, who pay their tribute towards the support of Great Britain. About the year 1559, the loss to the revenue, by collecting it in different parts of the city, was first discovered, and an act passed to compel people to land their goods in such places as were appointed by the commissioners of the revenue; and this was the spot fixed on: A custom-house was erected; which, being destroyed by the great fire, was rebuilt by Charles II. In 1718 it underwent the same fate, and was restored in its present form. Before the custom-house was established here, the principal place for receiving the duties was at Billingsgate. In 1268 the half year's customs for foreign merchandise in the city of London came only to £.75:6:10; the annual produce of the customs, ending in April 1789, amounted to £.3,711,126.

49
Trinity House.

In Water-lane, a little to the north-west of the custom-house, is the *Trinity-house*; a society founded in 1515, at a period in which the British navy began to assume a system. The founder was Sir Thomas Spert comptroller of the navy, and commander of the great ship Henry Grace de Dieu. It is a corporation, consisting of a master, four wardens, eight assistants, and eighteen elder brethren; selected from commanders in the navy and the merchants service; and now and then a compliment is paid to one or two of our first nobility. They may be considered as guardians of our ships, military and commercial. Their powers are very extensive: they examine the ma-

thematical children of Christ's hospital, and the masters of his majesty's ships; they appoint pilots for the river Thames; settle the general rates of pilotage; erect light-houses and sea-marks; grant licences to poor seamen, not free of the city, to row on the Thames; prevent foreigners from serving on board our ships without licence; punish seamen for mutiny and desertion; hear and determine complaints of officers and men in the merchants service, but liable to appeal to the judge of the court of admiralty; superintend the deepening and cleansing of the river Thames, and have under their jurisdiction the ballast-office; have powers to buy lands, and receive donations for charitable uses; and, in consequence, relieve annually many thousands of poor seamen, their widows, and orphans. It is in this house the business of the institution is carried on: but the mother-house is at Deptford, the corporation being named, "the master, wardens, and assistants of the guild or fraternity of the most glorious and undivided Trinity, and of St Clement, in the parish of Deptford Strand, in the county of Kent."

Between Aldgate and the Tower is the street called ⁵⁰the *Minories*, from some poor ladies of the order of nuns.

St Clare, or minoresse. They had been invited to London by Blanch queen of Navarre, and wife to Edmund earl of Lancaster, who founded a convent for them in 1293. On the suppression of the monasteries, it was converted into a dwelling-house for some of the nobility, and is now in the possession of the Dartmouth family. Till of late years, the Minories were but a despicable street; but have now been excellently rebuilt, and are as elegant as any in the city.

On the west side of the city-walls at this place, stood the house of the *Crutched or Crossed Friars*, an order instituted at Bologna in 1169, and of which a branch settled in England in 1244, where they were accommodated with an house in this place by two citizens named *Ralph Hofer* and *William Saberna*, who became members.

half-crown of state, in form like the square White Tower, and so exquisitely wrought, that the workmanship of modern times is in no degree equal to it. It is of gold, and used only on the king's table at the coronation. 14. A noble silver font, double gilt, and elegantly wrought, in which the royal family are christened.

15. A large silver fountain, presented to king Charles II. by the town of Plymouth, very curiously wrought; but much inferior in beauty to the above. Besides these, which are commonly shown, there are in the jewel office all the crown jewels worn by the princes and princesses at coronations, and a great variety of curious old plate.

The record office consists of three rooms, one above another, and a large round room, where the rolls are kept. These are all handsomely waincotted, the waincoat being framed into presses round each room, within which are shelves and repositories for the records; and for the easier finding of them, the year of each reign is inscribed on the inside of these presses, and the records placed accordingly. Within these presses, which amount to 56 in number, are deposited all the rolls, from the first year of the reign of king John to the beginning of the reign of Richard III. but those after this last period are kept in the Rolls Chapel. The records in the Tower, among other things, contain the foundation of abbeys and other religious houses; the ancient tenures of all the lands in England, with a survey of the manors; the original of laws and statutes; proceedings of the courts of common law and equity; the rights of England to the dominion of the British seas; leagues and treaties with foreign princes; the achievements of England in foreign wars; the settlement of Ireland, as to law and dominion; the forms of submission of some Scottish kings for territories held in England; ancient grants of our kings to their subjects; privileges and immunities granted to cities and corporations during the period above mentioned; enrolments of charters and deeds made before the Conquest; the bounds of all the forests in England, with the several respective rights of the inhabitants to common pasture, and many other important records, all regularly disposed, and referred to in near a thousand folio indexes. This office is kept open, and attendance constantly given, from seven o'clock till one, except in the months of December, January, and February, when it is open only from eight to one, Sundays and holidays excepted. A search here is half a guinea, for which you may peruse any one subject a year.

members of their order. Henry VIII. granted their house to Sir Whomas Wyatt the elder, who built a handsome mansion on part of the ground where it stood. This mansion became afterwards the residence of John Lord Lumley, a celebrated warrior in the time of Henry VIII. In process of time, it was converted into a navy-office: but this office being removed to Somerset-house, the India Company have erected in its place a most magnificent warehouse, in form of an oblong square of about 250 feet by 160, including a court of 150 by 60 feet, the entrance to which is by an arched gateway.

52
Billinggate
Billinggate ward is distinguished by its market. *Billinggate* was a small port for the reception of shipping, and for a considerable time the most important place for the landing of almost every article of commerce. In the time of King William, Billinggate began to be celebrated as a fish-market. In 1699 it was by act of parliament made a free port for fish to be sold there every day except Sunday; but Mr Pennant informs us, that the object of this has long been frustrated, and that fish are now no longer to be had there in perfection. The same author gives a list of the fish which in the time of Edward III. were brought to the London market; the monarch himself having confederated to regulate the prices, that his subjects might not be imposed upon by those who sold them. Among these were the conger-eel and porpoise, neither of which is now admitted to any table. A pike at that time cost 6s. 8d.; whence our author concludes, that it was an exotic fish, and brought over at a vast expence. Some fishes are mentioned in his list with which this naturalist owns himself unacquainted, *viz.* the *barkey, bran, barleie, cropling, and rumb*. In Archbishop Nevill's great feast is mentioned also a fish named *thirle-poele*, unknown at present. Seals were formerly accounted a fish; and these, together with the sturgeon and porpoise, were the only fresh fish permitted by the 33d of Henry VIII. to be bought of any stranger at sea between England, France, Flanders, and Zealand.

53
Leadenhall.
Limestreet ward is remarkable for a very large building, of great antiquity, called *Leadenhall*, with flat battlements leaded on the top, and a spacious square in the middle. In 1309 it was the house of Sir Hugh Nevil knight; in 1384, of Humphry Bohun Earl of Hereford; in 1408 it became the property of the celebrated Whittington, who presented it to the mayor and commonalty of London; and in 1419, a public granary was erected here by Sir Simon Eyre, a citizen and draper, who built it with stone in its present form. This granary was designed as a preservative against famine, and to be kept always full of corn, which design was for some time happily answered. The house came to be used for many other purposes besides that of a granary; as for keeping the artillery and arms of the city. Preparations for any kind of pageantry or triumph were also made here; and from its strength the place was considered as the chief fortrefs within the city in case of any popular insurrection, and was likewise the place from whence alms were distributed. In this edifice are warehouses for the sale of leather, Col-

London.
54
The Index
House.

chester baize, meal, and wool. Adjoining to Leadenhall is a market, thence called *Leadenhall market*, consisting of five considerable squares or courts, and reckoned one of the greatest markets in Europe for flesh and other provisions, as well as for leather, green hides, and wool. A little to the eastward is the *India-house*, built in 1726, on the spot occupied by Sir William Craven, mayor in 1610. According to Mr Pennant, this house "is not worthy of the lords of Indostan."

In Broadstreet is the *Bank of England*, a stone building, which occupies one side of Three-needle street. The centre, and the building behind, were founded in the year 1733; the architect George Sampson. Before that time the business was transacted in Grocers-hall. The front is a sort of vestibule; the base rustic, the ornamental columns above Ionic. Within is a court leading to a second elegant building, which contains a hall and offices, where the debt of above 250 millions is punctually discharged. Of late years two wings of uncommon elegance, designed by Sir Robert Taylor, have been added, at the expence of a few houses, and of the church of St Christopher's le Stocks. "The name of the projector of this national glory (says Mr Pennant), was Mr James Paterson of Scotland. This palladium of our country was in 1780 saved from the fury of an infamous banditti by the virtue of its citizens, who formed suddenly a volunteer company, and over-awed the miscreants; while the chief magistrate skulked, trembling in his mansion-house, and left his important charge to its fate. This important building has ever since been very properly guarded by the military; who, in passing through the city, have often given offence to many busy characters who would strive to preserve the city rights at the expence of the national destruction. A lord mayor was the last who interested himself by applying to Mr Grenville, who gave him to understand, that if the guards were not quietly permitted to discharge their duty, the bank would be removed to Somerset-house."

56
Mer-
chant-
Taylors
Hall, &c.
At the extremity of Three-needle street is *Mer-merchant-Taylors Hall*. In this street also is the *South-Sea House*, first established in 1711 for the purpose of an exclusive trade to the South Sea, and for supplying Spanish America with negroes.

Near the junction of Throgmorton street with Broad-street stood a magnificent house built by Cromwell earl of Essex; after whose fall, the house and gardens were bought by the Drapers company. The house was destroyed in the great fire, but rebuilt for the use of the company in a magnificent manner.

57
St Giles's
church
Mr Pennant informs us, that *St Giles's church* in the *St Giles's* fields, and a few houses to the west of it, in the year 1600, was barely separated from Broad-street. The church is supposed to have belonged to an hospital for lepers, founded about the year 1117, by Matilda queen to Henry I. In ancient times it was customary here to present to malefactors, on their way to the gallows (which, about the year 1413, was removed from Smithfield, and placed between St Giles's high-street and Hog-lane (c), a great bowl of ale, as the last refreshment they were to receive in this life. On

(c) This late place of execution, according to Mr Pennant, was called in the time of Edward III. when the

London. the door to the church-yard is a curious piece of sculpture, representing the last day, containing an amazing number of figures, set up about the year 1686. This church was rebuilt in 1625. By the amazing raising of the ground by filth and various adventitious matter, the floor in the year 1730 was eight feet below the surface acquired in the intervening time. This alone made it necessary to rebuild the church in the present century. The first stone was laid in 1730; it was finished in 1734, at the expence of 10,000*l*.—In the church-yard is a great square pit, with many rows of coffins piled one upon the other, all exposed to sight and smell, the latter of which is highly offensive if not dangerous.

On the west side of Broad-street stood the house of the Augustines, founded by Humphrey Bohun Earl of Somerset in 1253, for friars and hermits of the Augustine order. On the dissolution of the monasteries, great part of the house was granted to William Lord St John, afterwards Marquis of Winchester, and Lord Treasurer, who founded a magnificent house named *Winchester-house*. The west end of the church was granted in 1551 to John a Laico for the use of the Germans and other fugitive Protestants, and afterwards to the Dutch as a place for preaching. A part of it was also converted into a glass-house for Venice glass, in which the manufacture was carried on by artists from that city, and patronised by the Duke of Buckingham. The place was afterwards converted into *Pinners-hall*, belonging to the company of pin-makers.

To the eastward of Winchester-street stood the house of that very eminent merchant Sir Thomas Gresham, afterwards known by the name of *Gresham college*: (See GRESHAM.) It has been pulled down not many years ago; and the *Excise Office*, a most magnificent and at the same time simple building, rose in its place. Mr Pennant informs us, that from the 5th of January 1786 to January 5th 1787, the payments into this office amounted to no less than *L*.5,531,114 : 6 : 10*l*.

The *Royal Exchange*, which is the meeting-place of the merchants of London, stands in the ward of Cornhill, and is the finest and strongest fabric of the kind in Europe. It was founded in the year 1566. Sir Thomas Gresham, merchant in London, made an offer to the lord mayor and citizens, to build, at his own expence, a commodious edifice for merchants to meet and transact business, provided the city would find him a convenient situation for the same. Mr Pennant informs us, that one Richard Clough a Wellman, originally Sir Thomas's servant, first put him on this design by a letter from Antwerp, in which he reproached the London merchants with having no place to transact their business, but walking about in the rain, more like pedlars than merchants. The ci-

zens, in compliance with Sir Thomas's desire, purchased, for the sum of *L*.3532, 80 houses in the two alleys called *New St Christopher's*, and *Swan-alley*, leading out of Cornhill into Three-needle street. The materials of those houses were sold for *L*.478, and the ground, when cleared, was conveyed to Sir Thomas Gresham, who, accompanied by several aldermen, laid the first brick of the new building on the 7th of June that year. Each alderman also laid his brick, and left a piece of gold for the workmen; who set about it with such assiduity and resolution, that the whole fabric was roofed by the month of November 1567, and was soon after completed under the name of the *Burse*. This building was totally destroyed by the fire in 1666; and in its place the present magnificent structure was erected at the expence of *L*.80,000, which stands upon a plat of ground 203 feet in length and 171 in breadth, containing an area in the middle, of 61 square perches, surrounded with a substantial and regular stone building, wrought in rustic. It has two fronts, north and south, each of which is a piazza; and in the centre are the grand entrances into the area, under a very lofty and noble arch. The south-front in Cornhill is the principal; on each side of which are Corinthian demi-columns, supporting a compass pediment; and, in the intercolumniation on each side, in the front next the street, is a niche, with the statues of King Charles I. and II. in Roman habits, and well executed. Over the aperture, on the cornice between the two pediments, are the king's arms in relief: on each side of this entrance is a range of windows placed between demi-columns, and pilasters of the composite order, above which runs a balustrade. This building is 56 feet high: and from the centre, in this front, rises a lantern and turret 178 feet high, on the top of which is a fan of gilt brass made in the shape of a grasshopper, the crest of Sir Thomas Gresham's arms. The north front in Three-needle-street is adorned with pilasters of the composite order; but has neither columns nor statues on the outside; and has triangular, instead of compass, pediments. The inside of the area is also surrounded with piazzas, forming ambulatories for merchants, &c. to shelter themselves from the weather, when met there upon business. Above the arches of this piazza is an entablature with curious ornaments; and on the cornice a range of pilasters with an entablature extending round, and a compass pediment in the middle of the cornice of each of the four sides. Under the pediment on the north side are the king's arms; and the south, the city's arms; on the east, Sir Thomas Gresham's arms; and on the west, the mercer's arms, with their respective enrichments. In these intercolumns are 24 niches, 20 of which are filled with the statues of the kings and queens of England.

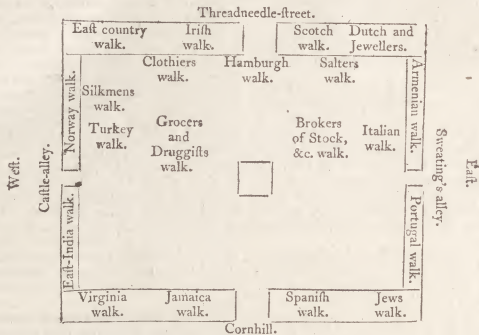

the gentle Mortimer finished his days here, the *Elms*: but the original as well as the present name was *Ty-bourne*; not from *tye* and *burn*, as if it were called so from the manner of capital punishments; but from *bourne*, the Saxon word for a "brook," and *Tye* the name of that brook, which joined gave name to a manor before the conquest. Here was also a village and church denominated *St John the Evangelist*, which fell to decay, and was succeeded by that of *Mary bourne*, corrupted into *Mary-la-bonne*. In 1626, Queen Henrietta Maria was compelled by her priests to take a walk by way of penance to Tyburn. What her offence was we are not told; but Charles was so disgusted at this insolence, that he soon after sent them and all her majesty's French servants out of the kingdom.

London. land. Under these piazzas, within the area, are 28 niches, all vacant but that in which Sir Thomas Gresham's statue is placed in the north-west angle, and that in the fourth-west, where the statue of Sir John Barnard was placed in his lifetime by his fellow-citizens to express their sense of his merit. The centre of this area also is ornamented with a statue of King Charles II. in a Roman habit, standing upon a marble pedestal about eight feet high, and encompassed with iron rails; which pedestal is enriched on the south side with an imperial crown, a sceptre, sword, palm-branches, and other decorations, with a very flattering inscription to the king. On the west side is a cupid

cut in relievo, resting his right hand on a shield with the arms of France and England quartered, and holding a rose in his left hand. On the north side is another cupid supporting a shield with the arms of Ireland; and on the east side are the arms of Scotland, with a cupid holding a thistle; all done in relievo: the whole executed by that able statuary Mr Gibbon.

In this area, merchants, and such as have business with them, meet every day at change hours; and for the more regular, and readier dispatch of business, they dispose of themselves into separate walks, according to the following plan.

North.

In building this expensive structure there was an eye not only to magnificence, and to accommodate the merchants, but also to reimburse the expence. For this reason a gallery was built over the four sides of the royal exchange. This was divided into 200 shops, which were let out to haberdashers, milliners, &c. and which for several years were well occupied. But these shops have now for a long time been deserted, and the galleries are let out to the Royal Exchange Assurance-office, the Merchant-seamens office, the Marine Society, and to auctioneers, &c. Under the whole area there are the finest dry vaults that can be found any where, which are let out to the East India company to deposit their pepper. In the turret is a good clock with four dials, which is well regulated ever day, so that it becomes a standard of time to all the mercantile part of the town; and it goes with chimes at three, six, nine, and twelve o'clock, playing upon twelve bells. The outside of this grand fabric suffers very much in its elegance from the shops that surround it, and are built within its walls; and which are occupied by bookbinders, toy-men, cutlers, hosiery, watch-makers, &c.

South of the Royal-exchange, and near the west extremity of Lombard-street, is the *General Post Office*, which is a handsome and commodious building.

In Walbrook ward is the *Mansion-house*, for the residence of the lord-mayor. This edifice was begun in 1739, and finished in 1753. It is built of Portland stone, with a portico of six fluted columns, of the Corinthian order, in the front. The basement story is very massy, and consists of rustic work; in the centre of it is the door, which leads to the kitchens, cellars, and other offices. On each side rises a flight of steps, leading up to the portico, in the middle of which is the principal entry. The stone balustrade of the stairs is continued along the front of the portico, and the columns support a large angular pediment, adorned with a group of figures in bas relief, representing the dignity and opulence of the city of London. It is an extreme heavy building, of an oblong form, and its depth is the long side, having several magnificent apartments, which are not, however, well lighted, on account of the houses that surround it.

Behind the mansion-house is *St Stephen's church*, in Walbrook, justly reputed the master-piece of the celebrated Sir Christopher Wren, and is said to exceed every modern structure in the world in proportion and elegance.

The mansion-house, and many adjacent buildings, stand on the place where the *Stock market* once stood. This took its name from a pair of stocks erected

London. ted near the spot in 1281; and was the great market of London for provisions during many centuries.

65 London-tion. In this ward is situated one of the most remarkable pieces of antiquity in London. It is a great stone, now standing in a cave on the north side of Canon-street, close under the fourth wall of St Swithin's church. It is called *London-stone*; and was formerly pitched edgewise on the other side of the street, opposite to where it now stands, fixed deeply in the ground, and strongly fastened with iron bars; but for the convenience of wheel-carriages it was removed to its present situation. This stone is mentioned so early as the time of Athelstan, king of the West Saxons, and has been carefully preserved from age to age. Of the original cause of its erection no memorial remains; but it is conjectured, that as London was a Roman city, this stone might be the centre, and might serve as an object from which the distance was computed to the other considerable cities or stations in the province.

66 Merchant-Tailors School. In Dowgate ward is a noted academy, called *Merchant-tailors School*, from its having been founded by the merchant-tailors company, in the year 1561. It was destroyed by the fire of London in 1666, but was rebuilt, and is a very large structure, with commodious apartments for the masters and ushers, and a fine library. Sir Thomas White, lord mayor of this city, having founded St John's college in Oxford in 1557, appointed this school as a seminary for it, and established at Oxford 46 fellowships for scholars elected from this school.

67 St Mary le Bow. The church of *St Mary le Bow*, in Cordwainers-street ward, is the most eminent parochial church in the city. It was originally built in the reign of William the Conqueror; and being the first church the steeple of which was embellished with stone arches or bows, took thence its denomination of *le Bow*. It was burnt down in the fire of 1666, but soon afterwards rebuilt. The steeple of this church is reckoned the most beautiful of its kind in Europe.

68 Guildhall. In Cheap ward is *Guildhall*, or the town-house of London. This was originally built in 1411, but so damaged by the great fire already mentioned, as to be rebuilt in 1669. The front has a Gothic appearance; and this character is also due to the two gigantic effigies which stand within the hall. The hall is 153 feet long, 50 broad, and 55 high, adorned with the royal arms, and those of the city and its companies, as well as with several portraits of English sovereigns and judges. In this building are many apartments for transacting the business of the city, besides one for each of the judicial courts, namely, that of the King's Bench, the Common-Pleas, and the Exchequer.

69 Cheap-side. In the year 1246 Cheapside was an open field, named *Crown-field*, from an inn with the sign of the crown. At that time, and even for 200 years afterwards, none of the streets of London were paved excepting Thames-street, and from Ludgate-hill to Charing-Cross.

70 Goldsmiths Hall. *Goldsmiths Hall* stands in Foster-lane, which opens into the west end of Cheap-side.—In this lane also is St Martin's le Grand, which, though surrounded by the city, was yet subject, near three centuries, to Westminster-Abbey. A fine college was built here

in 700 by Wythred king of Kent; and, about the year 1056, rebuilt and chiefly endowed by Ingelric and Edward, two noble brothers. In 1068, it was confirmed and made independent of every other ecclesiastical jurisdiction, even that of the pope himself not excepted; and its privileges were confirmed by succeeding monarchs. It was governed by a dean, and a number of secular canons. In this jurisdiction a magnificent church was erected, but pulled down in 1548, when the college was surrendered; after which a tavern was erected on the spot.

A little to the westward of Mary-le-Bow church The Cross (in the adjoining ward), stood the *Croft* and *Conduit* in the middle of the street. The former was built by Edward I. in 1290, in memory of his queen Eleanor, whose body was refted on that spot in its way to be buried. Originally it had the statue of the queen at full length, resembling exactly that at Northampton. Having at length fallen to decay, it was rebuilt in 1441 by John Hutherby mayor of the city, at the expense of several citizens, being now ornamented with various images, as those of the Resurrection, the Virgin Mary, &c. As the magnificent processions took this road, it was new-gilt at every public entry. After the Reformation, the images gave so much offence, that it was thought proper to substitute that of Diana in place of the Virgin Mary. This, however, was refted by Queen Elizabeth, who offered a reward for the discovery of the offenders. As she imagined that a cross, the symbol of the Christian religion, could not justly give offence to any professor of that religion, she ordered a cross to be placed on the summit, and gilt; but in 1643, the parliament ordered the demolition of all crosses and other marks of Romish superstition.

Splendid tournaments were held between the Cross and Sopers-lane in the year 1331; but as Queen Philippa and a great number of other ladies, dressed in rich attire, were sitting on the upper scaffolding to behold the sports, the feat gave way, and they suddenly fell down among the knights and others who stood below; many of whom were grievously hurt. The carpenters were saved from punishment by the intercession of the queen; but the king, to prevent accidents of the like nature, ordered a building of stone to be erected near Bow-church, from whence the queen and other ladies might behold such spectacles in safety. This was used for the same purpose till the year 1410, when Henry IV. granted it to certain mercers, who converted it into shops, warehouses, and other places necessary for their trade.

A small distance eastward from the Cross stood the Conduit, which served to fill the lesser ones with water brought by pipes from Paddington.—This stood on the spot where the old conduit was situated, which was founded in 1285, constructed of stone lined with lead, and rebuilt in 1479 by Thomas IIan one of the sheriffs. On some grand occasions, these conduits have been made to run with claret; as at the coronation of Anna Bullen.

On the north side of Cheapside stood the *Hospital* of *St Thomas of Acon*, founded by Fitz-Theobald de Hall. Helles, and his wife Agnes, sister to the famous Thomas à Becket. The hospital was built 20 years after the murder of Thomas; and such was his reputation

London.

for sanctity, that it was dedicated to him even before he was canonized, and that in conjunction with the Virgin Mary herself. The whole was granted by king Henry VIII. to the company of mercers. It was destroyed by the great fire in 1666; but rebuilt by the mercers company, who have their hall here.—Immediately to the east is a narrow street called the *Old Jewry*, which took its name from a great synagogue which stood here till the Jews were expelled the kingdom in 1291. After them an order of friars named *Frates de sacca*, or *de penitentia*, took possession of the synagogue; and in 1305, Robert Fitzwalter, the great banner-bearer of the city, requested that the friars might assign it to him; the reason of which probably was, that it stood near to his house, which was situated in the neighbourhood of the present Grocers-hall. The chapel was bought by the grocers from Fitzwalter in 1411 for 320 marks.

75
Blackwell
Hall.

In Blackwell or Basing-hall ward, is *Blackwell or Bakeswell hall*, which adjoins to Guildhall, and is the greatest mart of woollen cloth in the world. It was purchased of King Richard II. by the city; and has ever since been used as a weekly market for broad and narrow woollen cloths, brought out of the country. Formerly proclamations were issued to compel people to bring their goods into the hall, to prevent deceit in the manufactures, which might be productive of discredit in foreign markets, and likewise be the means of defrauding the poor children of Christ's hospital of part of the revenue which arose from the hallage of this great magazine. It suffered the general devastation in 1666; but was rebuilt in 1672, and is now a spacious edifice, with a stone front adorned with columns.

76
Sion College

Cripplegate-ward is remarkable for a college, called *Sion-college*, founded in 1627, on the site of Elsing-hospital (d) or priory, by Dr Thomas White vicar of St Dunstan's in the West, for the improvement of the London clergy; and with alms-houses, under their care, for 20 poor persons, 10 men and 10 women. In the year 1631, a charter was procured for incorporating the clergy of London, by which they were constituted fellows of the college; and out of the incumbents are annually elected, on Tuesday three weeks after Easter, a president, two deans, and four assistants, who are to meet quarterly, to hear a Latin sermon, and afterwards be entertained at dinner in the college-hall at the expence of the foundation. John Simpson rector of St Olaves, who superintended the building, added, at his own expence, for the use of the studious part of the London clergy, a library 120 feet long, and amply filled with books.

77
Barbers
Hall.

In this ward is a hall which belongs to the company of barber-surgeons, the professions of barber and surgeon being formerly exercised by the same person. It was built by the celebrated Inigo Jones, and the upper end is formed out of one of the towers or barbicans of London wall. The anatomical theatre is elliptical, and very finely contrived. This hall is now called *Barbers Hall*; the surgeons, who disdained to be

any longer associated with their ancient brethren, having obtained a separate charter, and built themselves a new hall in the Old Bailey.

London.

78
St Paul's
Cathedral.

Farringdon-ward Within, is distinguished by the most magnificent Protestant church in the world, the cathedral of *St Paul*. The best authority we have for the origin of this church, is from its great restorer Sir Christopher Wren. His opinion that there had been a church on this spot, built by the Christians in the time of the Romans, was confirmed: when he searched for the foundations for his own design, he met with those of the original *presbyterium*, or semicircular chancel, of the old church. They consisted only of Kentish rubble-stone, artfully worked, and consolidated with exceedingly hard mortar, in the Roman manner, much excelling the superstructure. He explodes the notion of there having been here a temple of Diana, and the discovery of the horns of animals used in the sacrifices to that goddess, on which the opinion had been founded, no such having been discovered in all his searches.

The first church is supposed to have been destroyed in the Dioclesian persecution, and to have been rebuilt in the reign of Constantine. This was again demolished by the pagan Saxons; and restored, in 603, by Sebert, a petty prince, ruling in these parts, under Ethelbert king of Kent, the first Christian monarch of the Saxon race; who, at the instance of St Augustine, appointed Melitus the first bishop of London. Erkenwald, the son of king Offa, fourth in succession from Melitus, ornamented his cathedral very highly, and improved the revenues with his own patrimony. He was most deservedly canonized: for the very litter, in which he was carried in his last illness, continued many centuries to cure fevers by the touch; and the very chips, carried to the sick, restored them to health!

When the city of London was destroyed by fire, in 1086, this church was built; the bishop Mauritius began to rebuild it, and laid the foundations, which remained till its second destruction, from the same cause, in the last century. Notwithstanding Mauritius lived twenty years after he had begun this pious work, and bishop Beaugaves enjoyed the see twenty more, yet such was the grandeur of the design, that it remained unfinished. The first had the ruins of the Palatine Tower bestowed on him, as materials for the building; and Henry I. bestowed on Beaugaves part of the ditch belonging to the Tower, which, with purchases made by himself, enabled him to inclose the whole with a wall. The same monarch granted, besides, that every ship which brought stone for the church, should be exempted from toll; he gave him also all the great fish taken in his precincts, except the tongues; and, lastly, he secured to him, and his successor the delicious tythes of all his venison in the county of Essex.

The style of the ancient cathedral was a most beautiful Gothic; over the east end was an elegant circular window; alterations were made in the ends of the

(d) This was founded by William Elsing mercer in 1329 (on the site of a decayed nunnery), for the support of 100 blind men. He afterwards changed it into a priory, and became himself the first prior, who with four canons-regular were to superintend the miserable objects.

London.

the two transepts, so that their form is not delivered down to us in the ancient plans; and from the central tower rose a lofty and most graceful spire. The dimensions, as taken in 1309, were these: The length six hundred and ninety feet; the breadth a hundred and twenty; the height of the roof of the west part, from the floor, one hundred and two; of the east part, a hundred and eighty-eight; of the tower, two hundred and sixty; of the spire, which was made of wood covered with lead, two hundred and seventy-four. The whole space the church occupied was three acres and a half, one rood and a half, and six perches.

We may be astonished at this amazing building, and naturally inquire what fund could supply money to support so vast an expence. But monarchs resigned their revenues resulting from the customs due for the materials, which were brought to the adjacent wharfs; they furnished wood from the royal forests: prelates gave up much of their revenues; and, what was more than all, by the pious bait of indulgences, and remissions of penance, brought in from the good people of this realm most amazing sums. Pope Innocent III. in 1257, gave a release of sixty days penance; the archbishop of Cologne gave, a few years before, a relaxation of fifty days; and Boniface, archbishop of Canterbury, forty days.

The high altar dazzled with gems and gold, the gifts of its numerous votaries. John king of France, when prisoner in England, first paying his respects to St Erkenwald's shrine, offered four basons of gold: and the gifts at the obsequies of princes, foreign and British, were of immense value. On the day of the conversion of the tutelary saint, the charities were prodigious, first to the souls, when an indulgence of forty days pardon was given, *vere penitentibus, contritis et confessis*; and, by order of Henry III. fifteen hundred tapers were placed in the church, and fifteen thousand poor people fed in the church-yard.

The holiness of this place did not prevent thieves and profligates of all denominations from lurking within the precincts, and committing, under the favour of the night, murders and every sort of crime. Edward I.

N 187.

gave the dean and canons permission to inclose the whole within a wall; and to have gates to be shut every night, to exclude all disorderly people. Within these walls, on the north-west side, was the bishop's palace. Froissart tells us, that after the great tournament in Smithfield, king Edward III. and his queen lodged here, on occasion of their nuptials (æ.) — In 1561, the noble spire was totally burnt by lightning, and never restored.

In consequence of the resolutions taken in 1620, by James I. to repair the cathedral, the celebrated Inigo Jones was appointed to the work. But it was not attempted till the year 1633, when Inigo laid the first stone, and Inigo the fourth. That great architect begun with a most notorious impropriety, giving to the west end a portico of the Corinthian order, beautiful indeed, to this ancient gothic pile; and to the ends of the two transept gothic fronts in a most horrible style. The great fire made way for the restoring of this magnificent pile in its present noble form by Sir Christopher Wren, an architect worthy of so great a design.

It is built of fine Portland stone, in form of a cross. On the outside are two ranges of pilasters, consisting of an hundred and twenty each; the lower range of the Corinthian order, and the upper of the composite. The spaces between the arches of the windows and the architrave of the lower order, are filled with a great variety of curious enrichments, as are also those above. On the north side is a portico, the ascent to which is by twelve steps of black marble, and its dome supported by six very large columns. Over the dome is a pediment, the face of which is engraved with the royal arms, regalia, and other ornaments. On the south is a portico, the ascent to which is by twenty-five steps, and its dome supported by six columns, corresponding with those on the north side. The west front is graced with a most magnificent portico, supported by twelve lofty Corinthian columns: over these are eight columns of the composite order, which support a noble pediment, crowned with its acroteria, and in this pediment is the history of St Paul's conversion, boldly carved in bas relief. The ascent to this portico

3

is

(E) Before this cathedral was the famous *Paul's Cross*, a pulpit formed of wood, mounted upon steps of stone, and covered with lead, in which the most eminent divines were appointed to preach every Sunday in the forenoon. To this place, the court, the mayor, and aldermen, and principal citizens, used to resort. The greatest part of the congregation sat in the open air; the king and his train had covered galleries; and the better sort of people were also protected from the injury of the weather; but the far greater part stood exposed in the open air: for which reason the preacher went in very bad weather to a place called the Shrouds; a covered space on the side of the church, to protect the congregation in inclement seasons. Considerable contributions were raised among the nobility and citizens, to support such preachers as were (as was often the case) called to town from either of the universities. In particular, the lord mayor and aldermen ordered that every preacher, who came from a distance, should be freely accommodated, during five days, with sweet and convenient lodgings, fire, candle, and all necessaries. And notice was given by the bishop of London, to the preacher appointed by him, of the place he was to repair to.

We hear of this being in use as early as the year 1259. It was used, as Mr Pennant observes, not only for the instruction of mankind by the doctrine of the preacher, but for every purpose political or ecclesiastical; for giving force to oaths, for promulging of laws, or rather the royal pleasure, for the emission of papal bulls, for anathematizing sinners, for benedictions, for exposing of penitents under censure of the church, for recantations, for the private ends of the ambitious, and for the defaming of those who had incurred the displeasure of crowned heads.

It was demolished in 1643 by order of parliament, executed by the willing hands of Isaac Pennington, the fanatical lord mayor of that year, who died in the Tower a convicted regeicide.

London. is by a flight of steps of black marble, extending the whole length of the portico; and over each corner of the west front is a beautiful turret. A vault dome, or cupola, rises in the centre of the building. Twenty feet above the roof of the church is a circular range of thirty-two columns with niches, placed exactly against others within. These are terminated by their entablature, which supports a handsome gallery, adorned with a stone ballustrade. Above the columns last mentioned is a range of pilasters, with windows between them: and from the entablature of these, the diameter of the dome gradually decreases. On the summit of the dome is an elegant balcony, from the centre of which runs a beautiful lanthorn, adorned with Corinthian columns. The whole is crowned with a copper ball, supporting a cross, both finely gilt. Within, the cupola stands on eight stupendous pillars, curiously adorned: the roof of the choir is supported by fix pillars, and that of the church by two ranges, consisting of twenty more. The roof of the church and choir is adorned with arches and spacious peripheries of enrichments, admirably carved in stone. Quite round the inside of the cupola, there is a whispering iron balcony, or gallery, the top of which is richly painted by Sir James Thornhill.

The first stone of this superb edifice was laid on June 21, 1675; and the building was completed in 1710; but the whole decorations were not finished till 1723. It was a most singular circumstance, that, notwithstanding it was 35 years in building, it was begun and finished by one architect, and under one prelate Henry Compton bishop of London. The church of St Peter's was 135 years in building, in the reigns of 19 popes, and went through the hands of twelve architects. It is not, as often mistaken, built after the model of that famous temple: it is the entire conception of our great countryman, and has been preferred in some respects, by a judicious writer, to even the Roman Basilica. Its dimensions are less. The comparative view is given in the Parentalia, and copied in London and its Environs. The height of St Peter's, to the top of the cross, is 437 feet and an half; that of St Paul's 340 feet; so that, from its situation, it is lofty enough to be seen from the sea. The length of the first is 729 feet; of the latter, 500. The greatest breadth of St Peter's is 364; of St Paul's, 180.

In the reigns of James I. and Charles I. the body of this cathedral was the common resort of the politicians, the news-mongers, and idle in general. It was called *Paul's walk*; and is mentioned in the old plays and other books of the times.

Notwithstanding the magnificence of this noble pile, however, it is remarked to have many defects. Its situation is such, that it cannot be viewed at a distance. The division of the porticos, and the whole structure into two stories on the outside, certainly indicate a like division within, which is acknowledged to be a fault. The dome, it has also been observed, bears too great a proportion to the rest of the pile, and ought to have been raised exactly in the centre of the building; besides that, there ought to have been two steeples at the east end, to correspond with those at the west. On entering this church, we instantly perceive an obvious deficiency, not only of elevation but length, to assist

the perspective; and the columns are heavy and clumsy, rather incumbering the prospect than enriching it.

St Paul's occupies an area of fix acres, and is raised all round with iron balustrades, each about five feet and an half high, fixed on a dwarf wall of hewn stone. In the west end of this area is a marble statue of Queen Anne, holding a sceptre in one hand, and a globe in the other, surrounded with four emblematical figures representing Great Britain, France, Ireland, and America.

Besides very large contributions for carrying on this edifice, the parliament granted a duty on sea-coal, which, at a medium, produced 5000 l. a-year; and the whole expence of the building is said to have amounted to 736,752 l. 2s. 3d.

On the east side of the cathedral is *St Paul's School*, founded in 1509 by Dr John Collet dean of this church, who endowed it for a principal-master, an under-master, a chaplain, and 153 scholars.

In Warwick-lane, in the same ward, stands the *College of Physicians*, erected in 1682 by Sir Christopher Wren. It is built of brick, and has a spacious stone frontispiece. Near the south extremity of the Old Bailey, on the east side, is the hall of the Company of Surgeons, with a theatre for dissection.

Adjoining to Christ-church in Newgate-street is *Christ's-Hospital*, which, before the dissolution of monasteries by Henry VIII. way a house of grey-friars. The hospital was founded by King Edward VI. for supporting and educating the fatherless children of poor freemen of this city; of whom 1000 of both sexes are generally maintained in the house or out at nurse, and are likewise clothed and educated. In 1673, a mathematical school was founded here by Charles II. endowed with L. 320 a-year; and a writing-school was added in 1694 by Sir John Moor, an alderman of the city. After the boys have been seven or eight years on the foundation, some are sent to the university and others to sea; while the rest, at a proper age, are put apprentices to trades at the charge of the hospital. At first their habit was a russet cotton, but was soon after changed for blue, which has ever since continued to be their colour; and on this account the foundation is frequently called the *blue-coat hospital*. The affairs of this charity are managed by a president and about 300 governors, besides the lord-mayor and aldermen. The fabric, which is partly Gothic and partly modern, was much damaged by the fire of 1666, but was soon repaired, and has been since increased with several additions. The principal buildings, which form the four sides of an area, have a piazza round them with Gothic arches, and the walls are supported by abutments. The front is more modern, and has Doric pilasters supported on pedestals.

In Cattle-Baynard ward is a large structure called *Doctors-Commons*. It consists of several handsome paved courts, in which the judges of the court of admiralty, those of the court of delegates, of the court of arches, and the prerogative court, with the doctors that plead causes, and the proctors of the place, all live in a collegiate way; and from commoning together, as in other colleges, the name of Doctors-Commons is derived. Here courts are kept for the trial of civil and ecclesiastical causes under the archbishop of Canterbury

London.

and the bishop of London. The college has an excellent library, every bishop at his consecration giving L. 20 or L. 50 towards purchasing books for it.

82
College of
Heralds.

Near Doctors-Commons, on St Bennet's Hill, is the *College of Heralds*, who were incorporated by King Richard III. Besides the chief officer, who is the earl-marshal of England, here are three kings at arms, *viz.* Garter, Clarenceux, and Norroy, with six heralds, four pursuivants, and eight proctors. Garter attends the infatuements of knights of that order, carries the garter to foreign princes, regulates the ceremonies at coronations, and the funeral of the royal family and nobility: Clarenceux directs the funeral ceremonies of those under the degree of peers south of Trent; and Norroy performs the like office for those north of Trent. This building was originally the house of the earl of Derby. It is a spacious quadrangle, built of brick, and has convenient apartments. Here are kept records of the coats of arms of all the families and names in England, with an account when they were granted, and on what occasion.

83
Bridewell.

In Farringdon-ward Without is a large building called *Bridewell*, from a spring formerly known by the name of St Bridget's or St Bride's-Well. It was originally a royal palace, and occupied all the ground from Fleet-ditch on the east to Water-lane on the west. That part of it now called *Salisbury-court* was given to the bishops of Salisbury for their town-residence; and the east part, which was rebuilt by King Henry VIII. is the present Bridewell. It was granted to the city by Edward VI. as an hospital; and he endowed it for the lodging of poor travellers, and for the correction of vagabonds, strumpets, and idle persons, as well as for finding them work. In one part of the building 20 artificers have houses; and about 150 boys, distinguished by white hats and blue doublets, are put apprentices to gloves, flax dressers, weavers, &c. and when they have served their time are intitled to the freedom of the city, with L. 10 towards carrying on their respective trades. The other part of Bridewell is a receptacle for disorderly persons, who are kept at beating hemp and other hard labour.

Near Bridewell is *St Bride's Church*, a stately fabric 111 feet long, 57 broad, and 41 high, with a beautiful spire 234 feet in altitude, and has a ring of 12 bells in its tower.

84
Blackfriars
Bridge.

Opposite to Fleet-ditch, over this part of the river, stands *Blackfriars Bridge*; a most elegant structure built after the design of Mr Robert Mylne. The situation of the ground on the two shores obliged the architect to employ elliptical arches; which, however, have a very fine effect. The number of arches is nine; of which the centre one is 100 feet wide. The whole length is 995 feet: the breadth of the carriage-way is 28 feet, and that of the two foot-ways 7 each. Over each pier is a recess; an apology for the beautiful Ionic pillars which support them, and which have a most beautiful effect from the river. This bridge was begun in 1760; and finished in 1768, at the expence of L. 152,840, to be discharged by a toll upon the passengers. It is situated almost at an equal distance between those of Westminster and London, commands a view of the Thames from the latter to Whitehall, and discovers the majesty of St Paul's in a very striking manner.

London.

85
Smithfield.

West Smithfield. In this ward is an area containing three acres of ground, called in old records *Smithfield-Pond* or *Horfe-Pool*, it having been formerly a watering place for horses. It was in ancient times the common place of execution; and at the south-west corner there was a gallows called the *Elms*, from a number of elm-trees that grew in the neighbourhood. It was likewise the scene of public jousts and tournaments, and has been a market-place for cattle above 500 years.

On the south-side of this area, and contiguous to Christ's hospital, is *St Bartholomew's Hospital*. It was originally founded soon after the accession of Henry I. by Rahere the king's jester, as an infirmary for the priory of St Bartholomew the Great, which then stood near the spot. But upon the dissolution of religious houses, Henry VIII. refounded it, and endowed it with 500 marks a year, on condition that the citizens should pay the same sum annually for the relief of 100 lame and infirm patients. The endowments of this charity have since been so much enlarged, that it now receives the distressed of all denominations. In 1702, a beautiful frontispiece was erected towards Smithfield, adorned with pilasters, entablature, and a pediment of the Ionic order, with a statue of King Henry VIII. standing in a niche in full proportion, and those of two cripples on the top of the pediment over it. In 1720, a plan was formed for rebuilding the rest of this hospital, in consequence of which a magnificent edifice has been erected.

Among many other privileges granted by Henry I. to the prior and canons of the monastery of St Bartholomew the Great, and to the poor of the infirmary, was that of keeping a fair in Smithfield on the eve, day, and morrow, of St Bartholomew. This fair, called *Bartholomew-fair*, has been held annually ever since; and by the indulgence of the magistrates of London, to whom the privilege of keeping it devolved upon the dissolution of the priory, it used to continue a fortnight. A great number of booths was erected in it by the actors of the theatres, for the exhibition of dramatic performances of various kinds; and it became at length a scene of so much licentiousness and riot, that Sir John Barnard when lord-mayor of London reduced the time of the fair to its original duration of three days. This laudable example has been followed ever since; and the magistrates have likewise prohibited all public exhibitions which had been formerly accompanied with so much disorder.

In a street in this ward, called the *Old Bailey*, is a hall named *Justice-hall*, or the *Sesſon's-house*, where a court is held eight times a year by the king's commission of oyer and terminer for the trial of criminals for offences committed within the city of London and county of Middlesex. The judges of this court are the lord-mayor, those of the aldermen that have served that office, and the recorder, who are attended by the sheriffs and by one or more of the national judges.

In this street is also the great criminal prison, lately built in a much more convenient situation, and on a more enlarged plan than the former prison, called *Newgate*; by which name it is still distinguished. Here the unfortunate debtor will no longer be annoyed by the dreadful rattle of chains, or by the more horrid sounds issuing from the lips of those wretched beings who set defiance to all laws divine and human; and

88
Newgate.

London. and here also the offender, whose crime is not capital, may enjoy all the benefits of a free open air.

89
Fleet-prison.
In this ward is likewise a prison called the *Fleet-prison*, from a small river named the Fleet which formerly run by it: this building is large, and reckoned the best in the city for good rooms and other conveniences. It has the benefit of a large yard, which is enclosed with a very high wall. This prison is as ancient as the reign of Richard I. and belongs to the court of chancery, &c.

90
The Rolls
In Chancery-lane, in this ward, is an office consisting of a house and chapel, called the office and chapel of the *Rolls*, from being the great repository of the modern public rolls and records of the kingdom. This building was originally the house of an eminent Jew; but being forfeited to the crown, King Henry III. in the year 1223 converted it into an hospital for the reception and accommodation of Jewish and other profelytes. In 1377, Edward III. granted this hospital and its chapel to William Bursfall master of the rolls, to whose successors in that office it has ever since belonged. Round this office there is a small district consisting of about 200 houses, called the *Liberty of the Rolls*, over which the magistrates of London have no authority, it being under the government of the master of the rolls.

In this ward are several *Inns* of court and chancery, particularly the Inner and Middle-Temple, Serjeant's-Inn, Clifford's-Inn, Barnard's-Inn, Staples-Inn, and Furnival's-Inn.

91
The Temple.
The Temple received its name from being originally founded by the Knight's-Templars, who settled here in 1185. It was at first called the *New Temple*, to distinguish it from the former house of the Knight's-Templars, which stood in Holborn near Chancery-lane.

The original building was divided into three parts; the Inner, the Middle, and the Outer Temple. The Inner and the Outer Temple were so called, because one was within and the other was without the Bar; and the Middle derived its name from being situated between them. Upon the dissolution of the order of Knights-Templars, the New Temple devolved to the Knights-Hospitalers of St John of Jerusalem, who granted a lease of it to the students of the common law, and converted that part of it called Inner and Middle Temple into two inns of court for the study and practice of the common law. The Outer Temple became a house for the earl of Essex.

The buildings of the Temple escaped the fire in 1666, but were most of them destroyed by subsequent fires, and have since been rebuilt. The two Temples are each divided into several courts, and have pleasant gardens on the banks of the Thames. They are appropriated to distinct societies, and have separate halls, where the members dine in common during term-time. The Inner-Temple hall is said to have been built in the reign of Edward III. and the Middle-Temple hall, which is a magnificent edifice, was rebuilt in 1572 in form of a college-hall. The Middle-Temple gate, Mr Pennant informs us, was erected by Sir Amias Powlet on a singular occasion. It seems that Sir Amias, about the year 1501, thought fit to put Cardinal Wolsey, then parson of Lymington, into the stocks. In 1515, being sent for to London by the cardinal on

account of that ancient grudge, he was commanded not to quit town till farther orders. In consequence, he lodged five or six years in this gateway, which he rebuilt; and to pacify his cminence, adorned the front with the cardinal's cap, badges, cognifiance, and other devices of this butcher's son: so low were the great men obliged to stoop to that meteor of the times! Each temple has a good library, adorned with paintings and well furnished with books. An assembly, called a *parliament*, in which the affairs of the society of the Inner-Temple are managed, is held there every term. Both Temples have one church, first founded in 1185 by the Knights-Templars; but the present edifice is supposed to have been built in 1420. It is supported by neat slender pillars of Suffex marble, and is one of the most beautiful Gothic structures in England. In this church are many monuments, particularly of nine Knights-Templars cut in marble in full proportion, some of them seven feet and a half long; six are cross-legged, and therefore supposed to have been engaged in the crusades. The minister of this church, who is usually called the *master of the Temple*, is appointed by the benchers or senior members of both societies, and presented by a patent from the crown. Shakespeare (whether from tradition or history) makes the Temple garden the place in which the badge of the white and red rose originated; the distinctive badge of the houses of York and Lancaster, under which the respective partizans of each arranged themselves in the fatal quarrel which caused such torrents of English blood to flow.

Near the Temple-bar is the *Devil Tavern*, so called from its sign of St Dunstan seizing the evil spirit by the nose with a pair of hot tongs. Ben Jonson has immortalized it by his *Leges Conviviales*, which he wrote for the regulation of a club of wits held here in a room he dedicated to Apollo; over the chimney-piece of which they are preserved. The tavern was in his days kept by Simon Wadloe; whom, in a copy of verses over the door of the Apollo, he dignified with the title of *King of Skinkners*.

92.
Inns of Chancery.
Serjeant's-Inn is a small inn in Chancery-lane, where the judges and serjeants have chambers, but not houses, as they had in another inn of this name in Fleet-street, which they abandoned in 1730; but in each of them there is a hall and a chapel. *Clifford's-Inn* is an inn of chancery belonging to the Inner-Temple. It was originally a house granted by Edward II. to the family of the Cliffords, from which it derived its name; but was afterwards let upon lease to the students of the law, and in the reign of Edward III. sold to the members of this society. *Bernard's-Inn* is likewise an inn of Chancery belonging to Cray's-Inn. It stands in Holborn, and was the house of John Mackworth dean of Lincoln, who gave it to the professors of the law. *Staple's-Inn* belongs also to Gray's-Inn, and is situated in Holborn. It was once a hall for the merchants of the staple for wool, whence it derives its name; but it was purchased by the benchers of Gray's-Inn, and has been an inn of chancery since the year 1415. *Furnival's-Inn* is an inn of chancery belonging to Lincoln's-Inn, and was once the house of the family of the Furnivals, by whom it was let out to the professors of the law. It is a large old building, with a hall and a pleasant garden.

London.

93
Bethlehem
Hospital.

In Colman-street ward, on the south-side of a large square called *Moorfields*, stands *Bethlehem-hospital*, founded in 1675 by the lord-mayor and citizens of London for the reception and cure of poor lunatics. It is a noble edifice, built with brick and stone, and adorned with pilasters, entablatures, and sculpture; particularly with the figures of two lunatics over the grand gate, which are well executed. This building is 540 feet long and 40 broad, exclusive of two wings of a later erection, intended for the reception of such lunatics as are deemed incurable. This hospital contains a great number of convenient cells or apartments, where the patients are maintained and receive all medical assistance without any other expense to their friends than that of bedding. The structure is divided into two stories, through each of which runs a long gallery from one end of the house to the other. On the fourth side are the cells, and on the north the windows that give light to the galleries, which are divided in the middle by handsome iron-gates, to keep the men and women separate. This hospital being united to that of *Bridewell*, both are managed by the same president, governors, treasurer, clerk, physician, surgeon, and apothecary; but each has a steward and inferior officers peculiar to itself.

94
St Luke's
Hospital.

Opposite to Bethlehem-hospital stood that of *St Luke*, a long plain building, till of late appropriated to the same purposes, but wholly independent of the former. It was founded on the humane consideration that Bethlehem was incapable of receiving all the miserable objects which were offered. Of late years the patients were removed from the old hospital to a new one erected under the same name in Old-street, on the plan of the former, extending in front 393 feet. The old hospital is now pulled down, and replaced by a handsome row of houses. Uncured patients may be taken in again, by a very liberal regulation, on the payment of five shillings a week: so that their friends may, if they choose, try a second time the force of medicine on their unhappy relations or acquaintances.

95
Different
Markets.

Besides the three markets already mentioned at Smithfield for cattle and hay, at *Leadenhall* for butcher's meat, wool, hides, and Colchester baize, and at *Billinggate* for fish; there are in this city the following other markets, which are all very considerable, viz. *Honey-lane*, *Newgate*, and *Fleet-market*, chiefly for flesh, though with separate divisions for fish, butter, eggs, poultry, herbs, and fruit; and the *Three-Cranes* market, for apples and other fruit. The principal corn-market is held in a neat exchange situated in *Mark-lane*, and that for flour at *Queenthite*. In *Thames-street*, near *Billinggate*, there is an exchange for dealers in coals and masters of vessels in that trade to transact their business.

II. *The Borough of SOUTHWARK.* It was called by the Saxons *Suth*, or the "Southwork," in respect to some fort or fortification bearing that aspect from London. It was also called the *Borough*, or *Bury*, probably from the same reason. It was long inde-

pendent of the city of London: but, in consideration of the inconveniences arising from the escape of malefactors from the great capital into this place. it was in 1327 granted by Edward III. to the city on payment of L. 10 annually. It was then called the *village of Southwark*; it was afterwards styled the *bailiwick of Southwark*, and the mayor and commonalty of London appointed the bailiff. This power, however, not being sufficient to remedy the evil, a more intimate connection was thought necessary; and in the reign of Edward VI. on a valuable consideration paid to the crown, it was formed into a 26th ward, by the title of *Bridge-Ward Without*; with a reservation of certain privileges enjoyed there by the archbishop of Canterbury and some other ecclesiastics. In consequence of this, it was subjected to the lord-mayor of London, with the steward and bailiff. But Southwark being divided into two parts, this is to be understood of the division called the *Borough Liberty*, which consists of three of the parishes belonging to the town, with the greater part of a fourth parish. For the city division, the lord-mayor by his steward holds a court of record every Monday at the sessions-house on St Margaret's Hill in this borough for all debts, damages, and trespasses, within the limits of his jurisdiction.—The other division is called the *Clink*, or the *Manor of Southwark*, and is subdivided into the *Great Liberty*, the *Guild-hall*, and the *King's Manor*; for each of which subdivisions a court-leet is held, where the constables, ale-conners, and flesh-tasters, are chosen, and other business of this kind transacted. A court-house, called *Union-Hall*, has lately been built in the new street called *Union-street*, which leads in a direct line from the high-street in the Borough to Great Surry-street Blackfriars-road. The *Clink* liberty is under the jurisdiction of the bishop of Winchester, who, besides a court-leet, keeps here a court of record on the Bank-side near St Saviour's church by his steward or bailiff, for pleas of debt, damages, and trespasses. Courts-leet are also kept at Lambeth, Bermondsey, and Rotherhithe, three small districts adjoining to the Borough.—There is a counter for the imprisonment of offenders in the bailiwick, and another for the *Clink* liberty; to which may be added the *Surry* workhouse for vagrants. Besides these, there is the *Marshalsea-prison*, which is the county-gaol for felons, and the admiralty-gaol for pirates (G); in which is a court first erected for trials of causes between the king's domestics or menial servants, of which the knight-marshal is president, and his steward judge, to whom belong four counsellors and six attorneys; and the court is held every Friday by him or his deputy, for debt, damages, and trespasses, in causes for 10 miles round Whitehall, excepting London.—In this quarter is also the *King's-bench* prison, the rules of which are above two miles in circuit, and comprise the greatest part of St George's Fields. Here was committed Henry prince of Wales, afterwards King Henry V. by the spirited and honest judge Gascoigne, for striking or insulting him on the bench.

97
Courts.

98
Prisons.

(c) In 1377 this prison was broke open by a mob of sailors, who murdered a gentleman confined in it for killing one of their comrades, and who had been pardoned by the court. It was again broke open by Wat Tyler and his followers in 1381. It escaped in the infamous riots of 1780; while the King's-Bench, the Borough-prison, and the Clink-prison, were nearly at the same instant sacrificed to their fury.

London.

bench.

In this prison the allowance is somewhat better than that of the commons prisons; for which reason, many debtors remove themselves hither by *habeas corpus*. It is properly a place of confinement in all cases triable in the King's-bench court.—The first time that Southwark is mentioned in history is on occasion of Earl Goodwin's falling up the river to attack the royal navy of 50 ships lying before the palace of Westminster: this was in 1052, when we are told he went *ad Subworce*, and stayed there till the return of the tide.

99
Parishes,
&c.

Southwark consists of the parishes of St Olave, St Saviour, St George, and St Thomas; the parish of Christ-church, though contiguous to the borough, is in the county of Surry.

The principal church in Southwark is that of *St Saviour*, which was formerly a priory of regular canons. Being dedicated to the Virgin Mary, and situated near the bank of the Thames, it was called *St Mary Over Ree*, or *Overy*, by which appellation it is commonly known. This church is built in the manner of a cathedral, with three aisles from east to west, and a cross aisle. It is reckoned the largest parish-church in England, the three aisles first mentioned measuring 263 feet in length, and the cross aisle 109 feet. The height within is 47 feet, and it has a tower with four spires 150 feet high.

Not far from St George's church stood the magnificent palace of Charles Brandon duke of Suffolk, the deserved favourite of Henry VIII. After his death, in 1545, it came into the king's hands, who established here a royal mint. It at that time was called *Southwark Place*, and in great measure preserved its dignity. Edward VI. once dined in it. His sister and successor presented it to Heath archbishop of York, as an inn or residence for him and his successors whenever they repaired to London. As to the mint, it became a sanctuary for insolvent debtors; at length becoming the pest of the neighbourhood, by giving shelter to villains of every species that awakened the attention of parliament; which, by the statutes 8 and 9 Will. III. 9 George I. and 11 George I. entirely took away its abusive privileges.

100
Ancient
places of dis-
sent.

In the parish of Christ-church, near the water on Bankside, stood *Paris-garden*, one of the ancient play-houses of our metropolis. Ben Jonson is reproached by one Decker, an evasive critic, with his ill success on the stage, and in particular with having performed the part of Zuliman at Paris-garden. It seems to have been much frequented on Sundays. This profanation (Mr Pennant observes) was at length fully punished by the dire accident which befel the spectators in 1582, when the scaffolding suddenly fell, and multitudes of people were killed or miserably maimed. The omen seems to have been accepted; for in the next century the manor of Paris-garden was erected into a parish, and a church founded under the name of Christ's.

Beyond this place of amusement were the Bear-garden and place for baiting of bulls, the *British circi*: "Herein (says Stow) were kept bears, bulls, and other beasts to be bayted; as also mastives in several kennels nourished to bayt them. These bears and other beasts are there kept in plots of ground scaffolded about for the beholders to stand safe." This was then

London.

an amusement for persons of the first rank: our great, if not good, Elizabeth caused the French ambassadors to be carried to this theatre, to divert them with these bloody spectacles.

Not far from these scenes of cruel pastime was the *Bordello* or *Stews*, permitted and openly licensed by government, under certain laws or regulations. They were farmed out. Even a lord-mayor did not disdain to own them; but rented them to the *Froes*, that is "the bawds," of Flanders. Among other singular regulation, no freeholder was to admit married women; nor were they to keep open their houses on Sundays; nor were they to admit any women who had on them the perilous infirmity of burning. These infamous houses were very properly suppressed in the reign of Henry VIII.

The bishop of Winchester had formerly a palace here with a park (the same that is now called *Southwark-park*), which is since converted into warehouses and tenements, held by lease from the bishops of that see.

Besides several alms-houses, there are here *St Thomas's* and *Guy's hospitals*, two of the noblest endowments in England. The former was first erected in 1215 by Peter de Rupibus bishop of Winchester, who endowed it with land to the amount of L.343 a year; from which time it was held of the abbots of Bermondsey, one of whom in 1428 granted a right to the master of the hospital to hold all the lands it was then in possession of belonging to the said abbot and convent, the whole revenue of which did not exceed L.266: 17: 6 *per annum*. In the year 1551, after the citizens of London had purchased of Edward VI. the manor of Southwark and its appurtenances, of which this hospital was a part, they expended L.1100 in repairing and enlarging the edifice, and immediately received into it 260 patients; upon which the king in 1553 incorporated this hospital with those of Christ-church and Bridewell in the city of London. The building being much decayed, three beautiful squares adorned with colonades were erected by voluntary subscription in 1693, to which in 1732 the governors added a magnificent building, consisting of several wards with proper offices. The annual disbursements of this hospital have for many years amounted to L.8000. The house is divided into 19 wards, and is said to contain 474 beds.

Adjoining to St Thomas's stands *Guy's hospital*, perhaps the most extensive charitable foundation that ever was established by one man in private life. The founder of this hospital was Thomas Guy, a bookseller in Lombard-street, London, who lived to see the edifice roofed in; and at his death, in 1724, left L.238,292, 16s. including the expence of the building, to finish and endow it. This hospital consists of two capacious squares, containing 12 wards and 435 beds. It was incorporated by charter from parliament, and the first governors were appointed in 1725.

In St George's Fields, westward of the King's-bench prison, is the *Magdalen hospital* for the reception of penitent prostitutes; a little farther is situated the *Asylum* for orphan girls; and not far distant is the Westminster Lying-in hospital: Institutions, of which the following feeling and animated account is given by Mr Pennant.

111
The Stews.

112
St Thomas's
Hospital.

113
Gray's Hos-
pital.

"The

London.

114
The Asylum.

"The *Asylum* is an institution of a most heavenly nature, calculated to save from perdition of soul and body the brighter part of the creation; such on whom Providence hath bestowed angelic faces and elegant forms, designed as blessings to mankind, but too often debased to the vilest uses. The hazard that these innocents constantly are liable to from a thousand temptations, from poverty, from death of parents, from the diabolical procures, and often from the stupendous wickedness of parents themselves, who have been known to sell their beautiful girls for the purpose of prostitution, induced a worthy band to found in the year 1758 the *Asylum* or House of Refuge. Long may it flourish, and eternal be the reward of those into whose minds so amiable a conception entered!

115
The Magdalen Hospital.

"To afford means of salvation to those unhappy beings who had the ill fortune to lose the benefits of this divine institution, the *Magdalen Hospital* was instituted for the reception of the penitent prostitutes. To save from vice, is one great merit. To reclaim and restore to the dignity of honest rank in life, is certainly not less meritorious. The joy at the return of one sinner to repentance is elicited by the highest authority worthy of the heavenly host. That ecstasy, I trust, this institution has often occasioned. Since its foundation in the same year with the former, to December 25th, 1786, not fewer than 2471 have been admitted. Of these (it is not to be wondered that long and evil habits are often incurable) 300 have been discharged, uneasy under constraint; 45 proved lunatics, and afflicted with incurable fits; 60 have died; 52 never returned from hospitals they were sent to; 338 discharged for faults and irregularities. How to be dreaded is the entrance into the bounds of vice, since the retreat from its paths is so difficult! Finally, 1608 prodigals have been returned to their rejoicing parents; or placed in reputable services, or to honest trades, banes to idleness, and securities against a future relapse."—Into this charity, every woman who has been seduced (and is not pregnant or diseased), whether recommended or not, may apply for admission to the committee, who meet for that purpose on the first Tuesday in every month.

116
Lying-in Hospital.

Akin to those charities is that of the *Lying-in Hospital*: which is not intended merely for the reception of "the honest matron who can deposit her burden with the consciousness of lawful love; but also for the unhappy wretches whom some villain in the unguarded moment has seduced, and then left a prey to desertion of friends, to poverty, want, and guilt. Left such 'may be driven to despair by such complicated misery, and be tempted to destroy themselves and murder their infants,' here was founded in 1765 this humane preventative the Westminster New Lying-in Hospital, in which every assistance and accommodation requisite in such situations are provided in the most attentive and liberal manner. To obviate all objection to its being an encouragement to vice, no one is taken in a second time: but this most excellent charity is open to the worthy distressed matron as often as necessity requires. None are rejected who have friends to

recommend. And of both descriptions upwards of 4000 have experienced its salutary effect."

London.

St George's Fields are now almost covered with new-erected buildings, from the ditch at the end of St George's Great Surry-street, or Burrow's buildings, to the Fishmongers almshouses, in one direction; and from the Marshalsea-prison to the Dog and Duck, in the other direction; with several irregular indentations in its circumference: And where the principal roads meet an obelisk has been erected, pointing out the distance it stands from different parts of London, Westminster, and Blackfriars bridges. Among the buildings which serve to embellish and improve this entrance to London, Chatham square and Bridgestreet Blackfriars may be particularly specified.

118
Lambeth Palace.

At *Lambeth*, the archbishops of Canterbury have had a palace. According to Mr Pennant, it was in the earlier times a manor, possibly a royal one; for the great Hardknut died here in 1042, in the midst of the jollity of a wedding dinner; and here, without any formality, the usurper Harold is said to have snatched the crown and placed it on his own head. At that period it was part of the estate of Goda, wife to Walter Earl of Mantes, and Eustace Earl of Boulogne; who presented it to the church of Rochester, but reserved to herself the patronage of the church. It became in 1197 the property of the see of Canterbury, by exchange transacted between Glanville Bishop of Rochester, and the Archbishop Hubert Walter. The building was improved by Langton the successor of Walter; but it was afterwards neglected and became ruinous. "No pious zeal (says Mr Pennant) restored the place, but the madnels of priestly pride. Boniface, a wrathful and turbulent primate, elected in 1244, took it into his head to become a visitor of the priory of St Bartholomew, to which he, had no right. The monks met him with reverential respect, but assured him the office did not belong to the bishop. The meek prelate rushed on the subprior, knocked him down, kicked, beat, and buffeted him, tore the cope off his back, and stamped on it like one possessed, while his attendants paid the same compliments to all the poor monks. The people enraged at his unpriestly conduct would have torn him to pieces; when he retired to Lambeth, and, by way of expiation, rebuilt it with great magnificence.—At a subsequent period it was very highly improved by the munificent Henry Chicheley, who enjoyed the primacy from 1414 to 1443. I lament to find so worthy a man to have been the founder of a building so reproachful to his memory as the Lollards tower, at the expence of near L. 280. Neither Protestants or Catholics should omit visiting this tower, the cruel prison of the unhappy followers of Wickliffe. The vaulted staples and rings to which they were chained before they were brought to the stake, ought to make Protestants bless the hour which freed them from so bloody a religion." During the civil wars of the last century, this palace suffered greatly; but at the restoration, the whole was repaired by Archbishop Juxton.

The parish church of Lambeth (H), which is at a small distance

(H) In describing this church, Mr Pennant takes occasion to mention the sad example of fallen majesty in the person of Mary d'Este, the unhappy queen of James II.; who flying with her infant prince from the ruin

London.

distance from the palace, has a plain tower; and the architecture is of the gothic of the time of Edward IV. It has very little remarkable in it, except the figure of a pedlar and his dog, painted in one of the windows; and tradition says, that the parish was obliged to this man for the bequest of a piece of land, which bears the name of *the Pedlar's Acre*. In the churchyard is the tomb of old Tradescant. Both father and son were great travellers; and the former is supposed to have visited Russia and most parts of Enrope, Turkey, Greece, many of the eastern countries, Egypt, and Barbary; out of which he introduced multitudes of plants and flowers, unknown before in our gardens. The monument is an altar tomb; embellished with emblematical sculptures; and bearing the following inscription, which is both singular and historical:

Know, stranger, ere thou pass, beneath this stone
Lye John Tradescant, grandfire, father, son;
The last dy'd in his fang; the other two
Liv'd till they had travell'd Art and Nature through,
As by their choice collection may appear,
Of what is rare, in kind, in sea, in air;
Whilst they (as Homer's Iliad in a nut)
A world of wonders in one closet flut:
These famous Antiquarians, that had been
Both gardeners to the Rose and Lily Queen,
Transplanted now themselves, sleep here; and when
Angels shall with their trumpets wake men,
And fire shall purge the world, these hence shall rise,
And change this garden for a paradise.

120
Lambeth-
marsh.

From Lambeth, eastward along the river side, was once a long tract of dreary marsh, and still in parts called *Lambeth-marsh*; about the year 1660, there was not a house on it from Lambeth palace as far as Southwark. In a street called *Narrow-wall* (from one of the ancient embankments) is Mrs Conde's noted

manufactory of artificial stone (1): And at a small distance, Mess. Beaufoy's great work for making wines (κ), and that for making vinegar (λ).

This ground, so profitable to the proprietors, and so productive of revenue to the state, was within memory the scene of low dissipation. Here stood Cuper's garden, noted for its fire-works, and the great resort of the profligate of both sexes. This place was ornamented with several of the mutilated statues belonging to Thomas Earl of Arundel, which had been for that purpose begged from his lordship by one Boyder Cuper, a gardener in the family. The great timber-yards beneath which these antiquities were found, are very well worthy of a visit. One would fear that the forests of Norway and the Baltic would be exhausted, to supply the want of our overgrown capital, were we not assured that the resources will successively be increasing equal to the demand of succeeding ages.— In this parish are also the vast distilleries, till of late the property of Sir Joseph Mawbey; where are seldom less than 2000 hogs constantly grunting, and kept entirely on the grains.

III. *City and Liberties of WESTMINSTER.* The city of Westminster derives its name from a *minster*, or abbey, and *west*, on account of its situation with respect to St Paul's cathedral, which was formerly called *Eastminster*. In ancient times this district stood upwards of a mile from the city of London, and contained only two parishes, which were those of St Margaret and St John, with two chapels of ease, but at present it has seven other parochial churches, viz. St Clement's Danes, St Paul's Covent-garden, St Mary's-le-Strand, St Martin's in the Fields, St Anne's, St James's, and St George's Hanover-square.

Westminster

ruin impending over their house, after crossing the Thames from the abdicated Whitehall, took shelter beneath the ancient walls of this church a whole hour, from the rain of the inclement night of December 6th, 1688. Here he waited with aggravated misery, till a common coach, procured from the next inn, arrived, and conveyed her to Gravesend, from whence she failed, and bid an eternal adieu to these kingdoms.

(1) Her repository consists of several very large rooms filled with every ornament which can be used in architecture. The statue, the vase, the urn, the rich chimney-pieces, and, in a few words, every thing which could be produced out of natural stone or marble by the most elegant chisel, is here to be obtained at an easy rate.

(κ) "Where (says Mr Pennant) the foreign wines are most admirably mimicked. Such is the prodigality and luxury of the age, that the demand for many sorts exceeds in a great degree the produce of the native vineyards. We have skillful fabricators, who kindly supply our wants. It has been estimated, that half of the port, and five-sixths of the white wines consumed in our capital, have been the produce of our home wine presses. The product of duty to the state from a single house was in one year, from July 5th 1785, to July 5th 1786, not less than L. 7,363: 9: 8½. The genial banks of the Thames opposite to our capital, yield almost every species of white wine; and by a wondrous magic, Mess. Beaufoy pour forth the materials for the rich Frontiniae, to the more elegant tables; the Maderia, the Calcavella, and the Lisbon, into every part of the kingdom."

(λ) "There is a magnificence of business (our author remarks) in this ocean of sweets and fours, that cannot fail exciting the greatest admiration: whether we consider the number of vessels or their size. The boasted tun at Heydelberg does not surpass them. On first entering the yard, two rise before you, covered at the top with a thatched dome; between them is a circular turret, including a winding staircase, which brings you to their summits, which are above 24 feet in diameter. One of these conservatories is full of sweet wine, and contains 58,109 gallons, or 1,815 barrels of Winchester measure. Its superb associate is full of vinegar, to the amount of 56,799 gallons, or 1,774 barrels of the same standard as the former. The famous German vessel yields even to the last by the quantity of 40 barrels.—Besides these, is an avenue of lesser vessels, which hold from 32,500 to 16,974 gallons each. After quitting this Brobdingnagian scene, we pass to the acres covered with common barrels: we cannot diminish our ideas so suddenly, but at first we imagined we could quaff them off as easily as Gulliver did the little hogheads of the kingdom of Lilliput."

133
Govern-
ment of
Westmin-
ster.

Westminster was anciently called Thorny-island, from its having been covered with thorn-bushes, and encompassed by a branch of the Thames, which is said to have run through the ground now called St James's-park, from west to east, and to have rejoined the river at Whitehall.

Till the general dissolution of religious houses, Westminster was subject to the arbitrary rule of its abbot and monks; but in 1541, upon the surrender of William Benson the last abbot, Henry VIII. not only turned it into an honour, but created it the see of a bishop, and appointed for a diocese the whole county of Middlesex, except Fulham, which belonged to the bishop of London. This bishoprick, however, soon after its institution, was dissolved by Edward VI.

The city of Westminster is governed by a high steward, an officer of great dignity, who is usually one of the first peers in the realm; and is chosen for life by the dean and chapter of the collegiate church of St Peter. There is also a deputy steward and a high bailiff, who also hold their offices for life; being nominated by the dean and chapter, and confirmed by the high steward.

The dean and chapter are invested with an ecclesiastical and civil jurisdiction within the liberties of Westminster, St Martin's-le-Grand, near Cheapside, in the city of London, and some towns in Essex, which are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury.

124
Churches.

St Margaret's church was founded by Edward the Confessor, since which time it has been frequently rebuilt. In the east end of this church is a window curiously painted, with the history of the crucifixion; and with the figures of several apostles and saints finely executed. It formerly belonged to a private chapel at Copt-hall, near Epping in Essex, and was purchased by the officers of this parish some years ago for 400 guineas. In this church the house of commons attends divine service on state holidays.

The church of *St John the Evangelist* was erected in 1778, and having sunk considerably whilst it was building, occasioned an alteration of the plan. On the north and south sides are magnificent porticoes, supported by vast stone pillars, as is also the roof of the church; at each of the four corners is a beautiful stone tower and pinnacle, which were added with the view of making the whole structure sink equally. The parts of this building are held together by iron bars, which run across even the aisles.

125
Westmin-
ster-abbey,
and its
chapels.

The most remarkable structure in Westminster is the *abbey-church of St Peter*. On its site stood once a temple of Apollo, which according to tradition was thrown down by an earthquake in the time of Antoninus Pius; and from the ruins of which, Sebert king of the West Saxons raised a Christian church, which was ruined by the Danes. It was repaired by Edward the Confessor, and given to a few monks; and this spot he chose for his burial-place. Henry III. 160 years after, took down this fabric of Edward's, and erected a new church, which was 50 years in building. It suffered much by fire in 1274, but was repaired by Edward I. Edward II. and the abbots. In 1700 this church being much decayed, the parliament granted money for repairing it, and has fre-

N° 187.

London.

quently repeated the bounty since that time. The form of the abbey is that of a long cross: its greatest length is 489 feet, and the breadth of the west front 66 feet; the length of the cross aisle is 189 feet, and the height of the roof 92 feet. At the west end are two towers: the nave and cross aisle are supported by 50 slender pillars of Sussex marble, exclusive of pillars. In the upper and lower ranges there are 94 windows, all which, with the arches, roofs, and doors, are in the Gothic taste. The inside of this church is much better executed than the outside: and the perspective is good, particularly that of the grand aisle. The choir, from which there is an ascent by several steps to a fine altar-piece, is paved with black and white marble; having 28 stalls on the north, the same number on the south, and eight at the west end. The altar is made of a beautiful piece of marble, the gift of Queen Anne, inclosed by a curious balustrade, and upon a pavement of porphyry, jasper, Lydian, and serpentine stones, laid in the Mosaic style, at the expense of abbot Ware, A. D. 1272; and is said to be one of the most beautiful of its kind in the world. On each side of this altar a door opens into St Edward's chapel; round which are 10 other chapels, ranging from the north to the south cross aisles, and are dedicated, 1. To St Andrew. 2. To St Michael. 3. To St John Evangelist. 4. Islop's chapel. 5. To St John Baptist. 6. To St Paul. 7. Henry V.'s chapel. 8. To St Nicholas. 9. To St Edmund. 10. To St Benedict.

In St Edward's chapel are still to be seen the remains of his shrine; which, though now in obscurity, and robbed of all its riches and lustre, was once esteemed the glory of England, so far as art and riches could make it. Here are the tombs of King Edward I. and several other kings and queens of England; and here also is shown the famous chair in which the kings of Scotland used to be crowned at Scoon. Henry V.'s chapel is divided from St Edward's by an iron screen, on each side of which are statues as big as life.—St Andrew's chapel, which is next the north cross, and the others which surround the choir, are crowded with the monuments of noble personages, worthy the attention of the curious.—At the corner of St Benedict's chapel, an iron gate opens into the south cross aisle; which from the number of monuments erected therein to celebrated English poets, has obtained the name of the *Poets corner*: though here we find a most magnificent monument erected at the fourth end in memory of the late John duke of Argyle and Greenwich; another to William Camden the antiquarian; and others to the celebrated divine Mr Isaac Barrow, to Thomas Parr who died at the age of 152 years, &c.—The south aisle is adorned with 19 curious monuments of the pious, the brave, and the learned; and turning northward from the west door, we view a great number more.

On the east of the abbey, and which, though separate from the other chapels in the choir, seems to Henry's chapel. 126
be one and the same building with the abbey, stands the chapel of King Henry VII. which that king founded in the year 1502, and was at that time styled the wonder of the world, and is now one of the most expensive remains of the ancient English taste and magnificence. There is no looking upon it without admiration.

^{London.} **miration**: it conveys an idea of the fine taste of Gothic architecture in that age: and the inside is so noble, majestic, and of such curious workmanship, that it would take a volume to describe each part with justice and propriety.

Its original intention was to be a dormitory for the royal blood: and so far the will of the founder has been observed, that none have been interred therein but such as have traced their descent from ancient kings. The tomb of King Henry VII. is most magnificent, inclosed with a screen of cast bras, most admirably designed, and as well executed. Within the rails are the figures of that king and his royal consort, in their robes of state, on a tomb of black marble: and at the head of this tomb lie the remains of Edward VI. In different parts of this chapel are the monuments of Lewis Stuart duke of Richmond, George Villars duke of Buckingham, John Sheffield duke of Buckingham, Charles Montague marquis of Halifax, Edward V. and his brother Richard; the vault of James I. and his queen Anne and daughter Mary, on which is a small tomb adorned with the figure of a child; a lofty monument of Queen Elizabeth, and another of Mary Queen of Scots; the monuments for Margaret Douglas daughter of Margaret queen of Scots, Margaret countess of Richmond mother to Henry VII. the vault of King Charles II. and William III. Queen Mary his consort, Queen Anne, and Prince George. Over these royal personages are their effigies (except that of prince George) in waincoat presses, made of wax to resemble life, and dressed in their coronation robes. And at the corner of the great east window, in another waincoat press, stands the effigy of Mary duchess of Richmond daughter to James duke of Richmond and Lenox, dressed in the very robes she wore at the coronation of Queen Anne. On leaving the aisle, you are shown another press, containing the effigy of general Monk, who, on account of his loyalty, and the part he took in the restoration of King Charles II. had a vault appropriated to him and his family amongst the royal blood.

In a fine vault under Henry the VII.'s chapel, is the burying-place of the present royal family, erected by his late majesty king George II. Adjoining to the abbey are the cloysters, built in a quadrangular form, with piazzas towards the court, where several of the prebendaries have their houses.

Near the abbey church is the King's school, usually called *Westminster School*. It was originally founded in 1070, and a second time by Queen Elizabeth in 1560, whence it is sometimes called the *Queen's College*; and is at present one of the greatest schools in the kingdom. The learned antiquary Mr Camden was once master of it, and Ben Jonson one of his scholars. Dr Busby, who was master upwards of 50 years, greatly contributed to keep up its reputation, formed its museum, and improved both the master's and his prebendal house.—This school, instead of one master and one usher as at first, has now an upper and under master, and five ushers, who have about 400 youths under their tuition. A plan was set on foot when the present archbishop of York was master, for building a college for the use of the students, but this did not succeed.

Vol. X. Part I.

On the north-east side of the abbey is an old Gothic building called *Westminster-hall*, first built by William Rufus as an addition to a royal palace, and afterwards rebuilt by Richard II. in the year 1397. It is reckoned one of the largest rooms in Europe, being 200 feet long, 70 broad, and 90 high, supported only by buttresses. The roof is of timber, and was some years ago slated, the old covering of lead being reckoned too heavy. It is paved with stone. In this spacious room the kings of England have generally held their coronation and other solemn feasts; and it is used for the trial of peers. Since the reign of Henry III. the three great courts of Chancery, King's Bench, and Common Pleas, have been held in separate apartments of this hall; and the court of Exchequer above stairs.

Adjoining to the south-east angle of Westminster-hall is a building formerly called *St Stephen's Chapel*, from its having been dedicated to that saint. It was founded by King Stephen; and in 1347 was rebuilt by King Edward III. who converted it to a collegiate church; but since it was surrendered to Edward VI. it has been used for the assembly of the representatives of the commons of England, and is now generally called the *House of Commons*. The benches, which ascend behind one another as in a theatre, are covered with green cloth; the floor is matted; and round the room are waincoat galleries, supported by cantilevers adorned with carved work, in which strangers are often permitted to sit and hear the debates.

On the south side of the hall is the *House of Lords*, so called from being the place where the peers of Great Britain assemble in parliament. It is an oblong room, not quite so large as the house of commons; and is hung with fine old tapestry, representing the defeat of the Spanish Armada in 1588. The design was drawn by Cornelius Vroom, and the tapestry executed by Francis Spiering. It was not put up till the year 1650, two years after the extinction of monarchy, when the house of lords was used as a committee-room for the house of commons. The heads of the naval heroes who commanded on the glorious day form a matchless border round the work, animating posterity to emulate their illustrious example. Here is a throne for the king, with seats on the right and left for such peers of the realm as are of the blood royal. Before the throne are three broad seats; on the first of which, next the throne, sits the Lord Chancellor, or keeper of the great seal, who is speaker of the house of peers; and on the other two sit the judges, the master of the rolls, or the masters in chancery, who attend occasionally to give their opinions on points of law. The two archbishops sit at some distance from the throne on the right hand, and the other bishops in a row under them. All the benches are covered with red cloth stuffed with wool. Here likewise, by a late order of the house, a gallery for strangers has been erected.

Adjoining to the house of lords is the *Prince's Chamber*, where the king is robed when he comes to the parliament. On the other side is the *Painted Chamber*, which is said to have been Edward the Confessor's bed-chamber, and the room in which the parliaments were anciently opened. Here conferences

London. are often held between the two houses, or their committees. Contiguous to those is an apartment called the *Court of Requests*, where such as have business in either house may attend.

¹³² Westminster bridge. Near these buildings is a bridge over the Thames, called *Westminster-bridge*, accounted one of the most complete and elegant structures of the kind in the known world. It is built entirely of stone, and extends over the river at a place where it is 1223 feet broad; which is above 300 feet broader than at London bridge. On each side is a fine ballustrade of stone, with places of shelter from the rain. The width of the bridge is 44 feet, having on each side a fine foot-way for passengers. It consists of 14 piers, and 13 large and two small arches, all semicircular, that in the centre being 76 feet wide, and the rest decreasing four feet each from the other, so that the two least arches of the 13 great ones are each 52 feet. It is computed that the value of 40,000l. in stone and other materials is always under water. This magnificent structure was begun in 1739, and finished in 1750, at the expence of 389,000l. defrayed by the parliament. It was built after the design of Monsi. Labeledy, an ingenious architect, a native of France.

¹³³ Whitehall. On the bank of the Thames, at the east confines of St Margaret's parish, was a palace called *Whitehall*, originally built by Hubert de Burgh earl of Kent, before the middle of the 13th century. It afterwards devolved to the archbishop of York, whence it received the name of *York Place*, and continued to be the city residence of the archbishops till it was purchased by Henry VIII. of cardinal Wolsey in 1530. At this period it became the residence of the court; but in 1697 was destroyed by accidental fire, all except the banquetting-house, which had been added to the palace of Whitehall by James I. according to a design of Inigo Jones. This is an elegant and magnificent structure of hewn stone, adorned with an upper and lower range of pillars, of the Ionic and Composite orders; the capitals are enriched with fruit and foliage, and between the columns of the windows. The roof is covered with lead, and surrounded with a balustrade. The building chiefly consists of one room of an oblong form, 40 feet high, and a proportionable length and breadth. The ceiling is painted by the celebrated Sir Peter Paul Rubens. It is now used only as a chapel-royal, and the other part of the house is occupied with state-offices.

¹³⁴ Horse-guards. Opposite to the banquetting-house stands the *Horse-guards*, so called from being the station where that part of His majesty's troops usually do duty. It is a strong building, of hewn stone, consisting of a centre and two wings. In the former is an arched passage into St James's Park; and over it, in the middle, rises a cupola. In a part of the building is the War-office. Near the Horse-guards is the *Treasury*; a large building, which fronts the Parade in St James's Park; and where the board of treasury is kept.

¹³⁵ Admiralty-office. Eastward of the Horse-guards is the *Admiralty-Office*, a large pile, built with brick and stone. The front towards Whitehall has two deep wings, and a lofty portico supported by four large stone pillars. A piazza, consisting of beautiful columns, runs almost

from one end to the other. The wall before the court has been lately built in an elegant manner, and each side of the gate is ornamented with naval emblems. Besides a hall, and other public apartments, here are spacious houses for seven commissioners of the admiralty.

At a little distance from the admiralty, where three capital streets terminate, is a large opening called *Charing-cross*, from one of the crosses which King Edward I. caused to be erected in memory of his queen Eleanor, and *Charing* the name of a village in which it was built. The cross remained till the civil wars in the reign of Charles I. when it was destroyed by the fanatics, as a monument of popish superstition; but after the Restoration, an equestrian statue of Charles I. was set up in its stead. This, which is of brass, and finely executed, continues to be an ornament to the place. It was made in 1633, at the expence of the Howard-Arundel family. The parliament sold it to a brazier in Holborn, with strict orders to break it to pieces; but he concealed it under ground till the Restoration, when it was set up in 1678.

¹³⁷ Palace. At the west end of the Mall, in St James's Park, Queen's Palace. It was originally known by the name of *Arlington-house*; but being purchased by the late duke of Buckingham's father, who rebuilt it from the ground in 1703, it was called *Buckingham-house*, till the year 1762, when it was purchased by his majesty for a royal residence. It is built of brick and stone, having in the front two ranges of pilasters of the Corinthian and Tuscan orders. It has a spacious court-yard, inclosed with iron rails, fronting St James's Park, with offices on each side, with two pavilions, separated from the mansion-house by colonades of the Tuscan, Doric, and Ionic orders. His majesty has here built a fine library, in an octagonal form, besides several other additions.

¹³⁸ Eastward of the queen's palace stands *St James's Palace*, an old building, which, till the former was purchased by the crown, had been the town-residence of the royal family since the burning of Whitehall in 1697. This palace was built by Henry VIII. and obtained its name from an hospital which formerly stood on the spot. It is an irregular building, of a mean appearance without, but contains several magnificent apartments. Here the court and levees are still kept, and most of the persons belonging to the household have their residence. The chapel of the hospital was converted to the use of the royal family, as it now remains, and is a royal peculiar, exempted from all episcopal jurisdiction. When this palace was built, it abutted in the south-west upon an uncultivated swampy tract of ground, which the king inclosed and converted into a park, called from the palace *St James's Park*. He also laid it out into walks, and collected the water into one body. It was afterwards much enlarged and improved by King Charles II. who planted it with lime trees, and formed a beautiful villa, near half a mile in length, called the *Mall*, from its being adapted to a play at bowls distinguished by that name. He also formed the water into a canal 100 feet broad and 2800 feet long; and furnished the park with a decoy, and other pond for water-fowl; but those have lately been

London. been destroyed, on account of the unwholesome vapours which they excited.

In a line with St James's palace, on the east side, is *Marlborough House*, which belongs to the duke of Marlborough, and is a large brick edifice, ornamented with stone.

¹⁴²
The Strand when first formed. Eastward from Charing-crofs, runs that fine street the *Strand*, which terminates at Temple-bar. In the year 1353 the whole of it was an open highway, with gardens to the water-side. In that year it was so ruinous, that Edward III. by an ordinance directed a tax to be raised upon wool, leather, wine, and goods carried to the staple at Westminster, from Temple-bar to Westminster abbey, for the repair of the road; and that all owners of houses adjacent to the highway should repair as much as lay before their doors. Before the above period, it entirely cut off Westminster from London; nothing intervened except the scattered houses, and a village which afterwards gave name to the whole; and St Martin's stood literally in the fields. But about the year 1560 a street was formed, loosely built; for all the houses on the south side had great gardens to the river, were called by their owners names, and in after-times gave name to the several streets that succeeded them, pointing down to the Thames; each of them had stairs for the convenience of taking boat, of which many to this day bear the names of the houses. As the court was for centuries either at the palace of Westminster or Whitehall, a boat was the customary conveyance of the great to the presence of their sovereign. The north side was a mere line of houses from Charing-crofs to Temple-bar; all beyond was country. The gardens which occupied part of the site of Convent-garden were bounded by fields, and St Giles's was a distant country village. Our capital found itself so secure in the vigorous government of queen Elizabeth, that, by the year 1600, most considerable additions were made to the north of the long line of street just described. St Martin's-lane was built on both sides. St Giles's church was still insulated: but Broad-street and Holborn were completely formed into streets with houses all the way to Snow-hill. Convent-garden and Lincoln's inn fields were built, but in an irregular manner. Drury-lane, Clare-street, and Long-acre, arose in the same period.

¹⁴¹
Northumberland House.

Almost contiguous to Charing-crofs, and upon the south side of the Strand, is that noble palace called *Northumberland-house*, which stands on the site of the hospital of St Mary Rouncival. Henry VIII. granted it to Sir Thomas Caverden. It was afterwards transferred to Henry Howard earl of Northampton; who, in the time of James I. built here a house, and called it after his own name. He left it to his kinsman the earl of Suffolk, lord treasurer; and by the marriage of Algernoon Percy earl of Northumberland, with Elisabeth daughter of Theophilus earl of Suffolk, it passed into the house of the present noble owner. The greater part of the house was built by Bernard Janfen, an architect in the reign of James I. The front next the street was begun by Algernoon in 1748, and finished by the present duke, who married his daughter. Two additional wings to the front next the Thames, and a variety of other improvements both

in building and furniture, have contributed to render this house the largest and most magnificent in London. It contains a gallery of 106 feet long by 26 wide most superbly furnished.

¹⁴²
Durham Yard.

A short way eastward, on the same side, stood *Dur-Durham-bam Tard*, which took its name from a place built originally by the illustrious Thomas de Hatfield, elected bishop of Durham in 1345; designed by him for the town residence of him and his successors. At this place, in 1540, was held a most magnificent feast, given by the challengers of England, who had caused to be proclaimed, in France, Flanders, Scotland, and Spain, a great and triumphant jousting to be holden at Westminster, for all comers that would undertake them. But both the challengers and defendants were English. After the gallant sports of each day, the challengers rode unto this Durham-house, where they kept open household, and feasted the king and queen (Anne of Cleves) with her ladies, and all the court. In the reign of Edward VI. the mint was established in this house, under the management of Sir William Shar- rington, and the influence of the aspiring Thomas Seymour, lord admiral. Durham-house was reckoned one of the royal palaces belonging to queen Elizabeth; who gave the use of it to the great Sir Walter Raleigh.

¹⁴³
The Adel- mas of building, called the *Adelphi*, in honour of phi- two brothers, the ingenious Adams, its architects. Besides its fine lodgings, it is celebrated for its enchanting prospect, the utility of its wharfs, and its subterraneous apartments answering a variety of purposes of general benefit.

¹⁴⁴
The Savoy. Farther on stand the ruins of the *Savoy*. Henry The Savoy, III. had granted to Peter of Savoy, uncle to his queen Eleanor, daughter of Berrenger of Provence, all the houses upon the Thames where this building now stands, to hold to him and his heirs, yielding yearly at the Exchequer three barbed arrows for all services. This prince founded the Savoy, and bestowed it on the foreign hospital of Montjoy. Queen Eleanor purchased it, and bestowed it on her son Edmund earl of Lancaster. It was rebuilt in a most magnificent manner by his son Henry. It was made the place of confinement of John king of France in 1356, after he was taken prisoner at the battle of Poitiers. In 1381 it was entirely destroyed by Wat Tyler, out of spleen to the great owner John of Gaunt. Henry VII. began to rebuild it, with a design of forming it into an hospital for a hundred distressed people, and Henry VIII. completed the design. The revenue at the suppression by Edward VI. amounted to above 500 l. a year. Queen Mary restored it; and her maids of honour, with exemplary piety, furnished it with all necessaries. It was again suppressed by Queen Elisabeth; and at present part serves as lodgings for private people, for barracks, and a scandalous infectious prison for the soldiery and for transport-convicts.

¹⁴⁵
Somerset-house. A little to the eastward stood *Somerset-house*, a palace built by Somerset the Protector in the time of Edward VI.; and to make way for which he demolished a great number of buildings without making any recompence to the owners. Part of the church of St John of Jerusalem and the Tower were blown up for

London.

the sake of the materials; and the cloisters on the north side of St Paul's, with the charnel-house and chapel, underwent the same fate; the tombs being destroyed, and the bones thrown into Finsbury-fields. This happened in 1549; but it is probable that he did not live to inhabit the palace he built, as he was executed in the year 1552. After his death the palace fell to the crown; and it became an occasional place of residence, first to Queen Elizabeth, and afterwards to Catherine queen to king Charles II. It was built in a style of architecture compounded of the Grecian and Gothic; and the back, front, and water-gate, were done from a design of Inigo Jones, about the year 1623. A chapel was begun the same year by that architect, and finished some time after. The whole of this structure was demolished in 1775, in consequence of an act of parliament; and a most magnificent edifice, from a design by Sir William Chambers, has been erected for the accommodation of all the public offices,—those of the Treasury, the Secretary of State, the Admiralty, the War, and the Excise, excepted. The Royal Society, and the Society of Antiquarians, hold their meetings here, in apartments which have been allotted to them by royal munificence; and here also are annually exhibited the works of the British painters and sculptors. The terrace on the south side is a walk bounded by the Thames, and unparalleled for grandeur and beauty of view.

146
St Martin's
and other
churches.

The church of St Martin is distinguished by the name of *St Martin's in the Fields*, from its situation, which was formerly a field, with only a few scattered houses. The church being decayed, was rebuilt by Henry VIII. and again by James I. but not being large enough to accommodate the inhabitants of the parish, it was augmented in 1637, at the charge of Prince Henry, eldest son of James I. and several of the nobility. After many expensive reparations, however, it was entirely taken down in 1720, and a new church began, which was finished in 1726. This is an elegant edifice, built of stone. On the west front is a noble portico of Corinthian columns, supporting a pediment, in which are represented the royal arms in bas relief. The ascent to the portico is by a flight of very long steps. The length of this church is about 140 feet, the breadth 60, and height 45. It has a fine arched roof sustained by stone columns of the Corinthian order. The steeple has a beautiful spire, and one of the best rings of bells in London.

St James's Church was built in the reign of Charles II. at the expence of Henry earl of St Alban's, and other neighbouring inhabitants. The building is of brick and stone, about 85 feet long, 60 broad, and 45 feet high, with a handsome steeple 150 feet in height.

St George's Church, near Hanover-square, is a beautiful structure. This was one of the fifty new churches erected within the bills of mortality, by act of parliament, in the reign of Queen Anne. The ground for the edifice was given by the late lieutenant-general Stewart, who also left 4000 l. to the parish, towards erecting and endowing a charity school; which, by additional benefactions and subscriptions, is become very considerable.

The greater part of the parish of *St Paul's Covent-*

garden, was anciently a garden, belonging to the abbey and convent of Westminster, and was then called *Convent-garden*, a name corrupted into Covent, and more generally Common-garden. In 1552, Edward VI. gave it to the earl of Bedford, with an adjoining field, formerly called the *Seven Acres*, but now, being turned into a long street, called *Long-acre*. The church of St Paul's, Covent-garden, was built by Inigo Jones, and is esteemed one of the most simple and perfect pieces of architecture in England. In the front is a plain portico of the Tuscan order, with massy columns. Before the church is a square area, containing about three acres of ground, called *Covent-garden market*, and is the best in England for herbs, fruit, and flowers. On the north, and part of the east side, is a magnificent piazza, designed by Inigo Jones.

Next to the parish of St Paul, Covent-garden, is that of *St Mary le Strand*. This is also one of the fifty new churches built in the reign of Queen Anne, and is a handsome piece of architecture, though not very extensive. At the entrance, on the west side, is an ascent by a flight of steps, in a circular form, which leads to a similarly shaped portico of Ionic columns, covered with a dome, that is crowned with a vase. The columns are continued along the body of the church, with pilasters of the same order at the corners; and in the intercolumniations are niches handsomely ornamented. Over the dome is a pediment supported by Corinthian columns, which are also continued round the body of the structure, over those of the Ionic order. A handsome balustrade is carried round the top of the church, and adorned with vases.

A little eastward from the preceding church is that of *St Clement's Danes*, situated likewise in the Strand. A church is said to have stood in this place since about the year 700; but the present structure was begun in 1680, designed by Sir Christopher Wren. It is built of stone, with two rows of windows, the lower plain, but the upper ornamented; and the termination is by an attic, the pilasters of which are covered with vases. On the fourth side is a portico, covered with a dome, supported by Ionic columns; and opposite to this is another. The steeple is beautiful, and of a great height.

The church of *St George, Bloomsbury*, is also one of the fifty new churches erected by act of parliament. It is distinguished from all the rest by standing south and north, and by the statue of King George I. at the top of its pyramidal steeple.

In Lamb's Conduit-fields, on the north side of the town, is a large and commodious structure called the *Foundling-hospital*, for the reception of exposed and deserted children. This laudable charity was projected by several eminent merchants in the reign of queen Anne; but was not carried into execution till many years afterwards, when a charter for its establishment was obtained, through the indefatigable assiduity of Mr Thomas Coram, the commander of a merchant vessel, who spent the remainder of his life in promoting this design. From the time of its institution, the parliament has occasionally granted considerable sums for its support; and in some years upwards of 6000 infants have been received.

Not far from hence is an *Hospital for the Small-pox*; and

London.

Foundling,
and other
Hospitals.

London.

and in different parts of the town there are others, either for the sick of all kinds, or those in particular circumstances. Of the latter are several *Lying-in hospitals*, and the *Lock-hospital* for female patients in the venereal disease. Of the former are *St George's* and the *Middlesex hospitals*, besides several infirmaries.

150
Gray's Inn.

Gray's Inn is one of the four principal inns of court; which, though situated within the limits of the parish of St Andrew, Holborn, is yet without the liberties of the city of London. It took its name from an ancient family of the name of Gray, which formerly resided here, and in the reign of Edward III. demised it to some students in the law; but it is said to have been afterwards conveyed to the monks of Shene, near Richmond in Surry, who leased it to the society of the Inn. It was held by this tenure till the dissolution of the monasteries, when Henry VIII. granted it to the society in fee-farm. This inn consists chiefly of two quadrangles, and has an old hall well built of timber, with a chapel in the Gothic style. Here is also a good library, and the Inn is accommodated with a spacious garden.

111
Lincoln's Inn.

Lincoln's Inn, another of the four principal inns of court, was originally the palace of Ralph Neville bishop of Chichester, and chancellor of England about the year 1226. It afterwards devolved to the earl of Lincoln, who converted it into a court for the students of law about the year 1310. From him it received the name of Lincoln's-inn, and consisted only of what is now called the old square, which is entered from Chancery-lane. At present this square contains, besides buildings for the lawyers, a large hall where the lord chancellor hears causes in the sittings after term. To this inn belongs likewise a fine garden, which has lately been diminished by the building of some large and commodious offices, for the use of the six clerks in the court of Chancery, &c.

152
Charter-house.

In the parish of St James, Clerkenwell, is an hospital called the *Charter-house*, which is a corruption of the word *chartreux*, a name formerly used for a convent or priory of the Carthusians, which this place formerly was. After the dissolution of monasteries it fell to the earl of Suffolk, who disposed of it to Thomas Sutton, Esq; a citizen of London, in the time of king James I. for L.13,000. The purchaser intending it for an hospital, applied to the king for a patent, which he obtained in 1611, and the grant was confirmed by parliament in 1623. Mr Sutton having expended L.7000 in fitting up the buildings, gave it the name of king James's hospital, and endowed it with lands to the amount of near L.4500 a-year, for the maintenance of 80 gentlemen, merchants or soldiers, who should be reduced to indigent circumstances; and 40 boys, to be instructed in classical learning. The men are provided with handsome apartments, and all the necessaries of life except clothes; instead of which each of them is allowed a gown, and L.7 a-year. Of the boys, 29 are at a proper time sent to the university, where each has an allowance of L.20 a-year for eight years. Others, who are judged more fit for trade, are put out apprentices, and the sum of L.40 is given with each of them. As a farther encouragement to the scholars, there are nine ecclesiastical preferments in the gift of the governors. It is also by

London.

the recommendation of the latter that all pensioners and youths are received into the hospital. They consist of 16, of which number the king is always one, and the others are generally noblemen of the first rank. To this hospital belong a master, a preacher, two schoolmasters, a physician, a regifter, a receiver, a treasurer, a steward, an auditor, and other officers; and the annual revenues of it being now increased to upwards of L.6000, five men and four boys have been added to the original number.

153
Alms-house
Hospital.

In the parish of St Luke stands the Haberdashers alms-house, or *Alke's Hospital*, so called from having been erected by the company of haberdashers, pursuant to the will of Robert Alke, Esq; one of their members, who left L.30,000 for the building and the relief of 20 poor members of the company; besides the maintenance and education of 20 boys, sons of decayed freemen of the same company. This is a large edifice of brick and stone, 400 feet long, with a piazza in front 340 feet in length, consisting of stone columns of the Tuscan order. In the middle of the building is a chapel, adorned with columns, entablatures, and pediment, of the Ionic order; and under the pediment is a niche, with a statue of the founder. In the same parish is the Iron-mongers hospital, likewise a large building.

In the parish of St Mary, Whitechapel, stands the *London Hospital*, for the reception of the sick. It is a large building, and was erected a few years since by voluntary contribution. Here are also some considerable alms-houses.

154
Houses of
the Nobility.

Within the precincts of Westminster are several stately houses belonging to the nobility, some of which have been already mentioned. Of the others, the most remarkable at present are, Burlington-house, Devonshire-house, Egremont-house, and Bedford-house; Carlton-house, the magnificent abode of the prince of Wales, and the superb residence erected by the duke of York between the Treasury and the Horse-guards.

155
British
Museum.

To these may be added, *Montagu-house* (now the British Museum); which was built on a French plan by the first duke of Montagu, who had been ambassador in France. The staircase and ceilings were painted by Rousseau and La Fosse: the apotheosis of Iris, and the assembly of the gods, are by the last. It was purchased of the duke's heirs by parliament, for uniting together the Royal, Cottonian, Harleian, Sloanian, and other collections of books, MSS. coins, antiquities, subjects in natural history, &c. &c. for the public use, for which it is excellently adapted. The first of these libraries contains the books and MSS. of our princes from Henry VII. to Charles II.; the second the MSS. collected by Sir Robert Cotton, his son, and grandson Sir John, which last gave it to the public by act 12 and 13 William III. c. 7. The Harleian collection of MSS. was formed by Edward earl of Oxford, and purchased by government in 1753, at the same time with the library, MSS. and natural curiosities of Sir Hans Sloane. This last cost Sir Hans L.50,000; and he left it, by will, to the use of the public, on condition that the parliament would pay L.20,000 to his executors. It comprehends an amazing number of curiosities: among which are, the library, including books of drawings, MSS. and prints,

amounting

London.

amounting to about 50,000 volumes; medals and coins, ancient and modern, 20,000; cameos and intaglios, about 700; seals, 268; vessels, &c. of agate, jasper, &c. 542; antiquities, 1125; precious stones, agates, jasper, &c. 2256; metals, minerals, ores, &c. 2725; crystal, spars, &c. 1864; fossils, flints, stones, 1275; earths, sands, salts, 1035; bitumens, sulphurs, ambers, &c. 399; tales, mice, &c. 388; corals, sponges, &c. 1421; testacea, or shells, &c. 5843; echini, echinits, &c. 659; alteriæ trochi, eutrochi, &c. 241; crustacea, crabs, lobsters, &c. 363; stella maris; star-fishes, &c. 173; fish, and their parts, &c. 1555; birds, and their parts, eggs, and nests, of different species, 1172; quadrupeds, &c. 1886; vipers, serpents, &c. 521; insects, &c. 5439; vegetables, 12,506; hortus ficus, or volumes of dried plants, 334; humani, as calculi, anatomical preparations, 750; miscellaneous things, natural, 2098; mathematical instruments, 55. A catalogue of all the above is written in a number of large volumes. It is a large and magnificent building; and has behind it a garden, consisting nearly of nine acres.

156
Principal
squares, &c.

Besides a great number of spacious streets, which are daily increasing, this part of the metropolis is ornamented with several magnificent squares, viz. Grosvenor-square, Berkeley-square, Portman-square, Cavendish-square, Hanover-square, St James's-square, Soho-square, Bloombury-square, Queen's-square, Lincoln's-Inn-fields, Leicester-square, Red-Lion-square, some of which have been particularly described; not to mention others that are at present building. In general, the new buildings in the liberty of Westminster have increased to a prodigious degree; inasmuch that they reach as far as Marybone to the north, Piccadilly to the south, and Hyde-Park-wall to the west.

157
London
anciently
inconven-
ient and un-
healthy.

Before the conflagration in 1666, LONDON (which, like most other great cities, had arisen from small beginnings) was totally inelegant, inconvenient, and unhealthy, of which latter misfortune many melancholy proofs are authenticated in history, and which, without doubt, proceeded from the narrowness of the streets, and the inaccountable projections of the buildings, that confined the putrid air, and joined with other circumstances, such as the want of water, rendered the city seldom free from pestilential devastation. The fire which consumed the greatest part of the city, dreadful as it was to the inhabitants at that time, was productive of consequences which made ample amends for the losses sustained by individuals; a new city arose on the ruins of the old; but, though more regular, open, convenient, and healthful, than the former, yet it by no means answered to the characters of magnificence or elegance, in many particulars; and it is ever to be lamented (such was the insatiation of those times), that the magnificent, elegant, and useful plan of the great Sir Christopher Wren, was totally disregarded, and sacrificed to the mean and selfish views of private property; views which did irreparable injury to the citizens themselves and to the nation in general: for had that great architect's plan been followed, what has often been asserted must have been the result; the metropolis of this kingdom would incontestably have been the most magnificent and elegant city in the

universe, and of consequence must, from the prodigious report of foreigners of distinction and taste who would have visited it, have become an inexhaustible fund of riches to this nation. But as the deplorable blindness of that age has deprived us of so valuable an acquisition, it is become absolutely necessary that some efforts should be made to render the present plan in a greater degree answerable to the character of the richest and most powerful people in the world.

The plan of London, in its present state, will in many instances appear to very moderate judges to be as injudicious a disposition as can easily be conceived for a city of trade and commerce, on the borders of so noble a river as the Thames. The wharfs and quays on its banks are extremely mean and inconvenient; and the want of regularity and uniformity in the streets of the city of London, and the mean avenues to many parts of it, are also circumstances that greatly lessen the grandeur of its appearance. Many of the churches and other public buildings are likewise thrust up in corners, in such a manner as might tempt foreigners to believe that they were designed to be concealed. The improvements of the city of London for some years past have, however, been very great; and the new streets, which are numerous, are in general more spacious, and built with greater regularity and elegance.

158
its plan still
defective.

The very elegant and necessary method of paving and enlightening the streets is also felt in the most sensible manner by all ranks and degrees of people. The roads are continued for several miles around upon the same model; and, exclusive of lamps regularly placed on each side, at short distances, are rendered more secure by watchmen stationed within call of each other. Nothing can appear more brilliant than those lights when viewed at a distance, especially where the roads run across; and even the principal streets, such as Pall Mall, New Bond-street, Oxford-street, &c. convey an idea of elegance and grandeur.

159
Great im-
provements.

London, then, in its large sense, including Westminster, Southwark, and part of Middlesex, forms one great metropolis, of vast extent and of prodigious wealth. When considered with all its advantages, it is now what ancient Rome once was; the seat of liberty, the encourager of arts, and the admiration of the whole world. It is the centre of trade; has an intimate connection with all the counties in the kingdom; and is the grand mart of the nation, to which all parts send their commodities, from whence they are again sent back into every town in the nation and to every part of the world. From hence innumerable carriages by land and water are constantly employed: and from hence arises that circulation in the national body which renders every part healthful, vigorous, and in a prosperous condition; a circulation that is equally beneficial to the head and the most distant members. Merchants are here as rich as noblemen; witness their incredible loans to government; and there is no place in the world where the shops of tradesmen make such a noble and elegant appearance, or are better stocked.

160
Wealth and
grandeur of
this vast
metropolis.

The Thames, on the banks of which London is situated, is a river which, though not the largest, is the richest and most commodious for commerce of any river.

161
its excellent
situation
for com-
merce.
in

London

in the world. It is continually filled with fleets, failing to or from the most distant climates : and its banks, from London-bridge to Blackwall, form almost one continued great magazine of naval stores ; containing three large wet-docks, 32 dry-docks, and 33 yards for the building of ships for the use of the merchants ; besides the places allotted for the building of boats and lighters, and the king's yards lower down the river for the building of men of war. As the city is about 60 miles distant from the sea, it enjoys, by means of this beautiful river, all the benefits of navigation, without the danger of being surpris'd by foreign fleets, or of being annoyed by the moist vapours of the sea. It rises regularly from the water-side, and, extending itself on both sides along its banks, reaches a prodigious length from east to west in a kind of amphitheatre towards the north, and is continued for near 20 miles on all sides, in a succession of magnificent villas and populous villages, the country-seats of gentlemen and tradesmen ; whither the latter retire for the benefit of fresh air, and to relax their minds from the hurry of business. The regard paid by the legislature to the property of the subject, has hitherto prevented any bounds being fixed for its extension.

162
Its great
extent.

The irregular form of London makes it difficult to ascertain its extent. However, its length from east to west is generally allowed to be above seven miles from Hyde-park corner to Poplar ; and its breadth in some places three, in others two, and in others again not much above half a mile. Hence the circumference of the whole is almost 18 miles ; or, according to a later measurement, the extent of continued buildings is 35 miles two furlongs and 39 rods. But it is much easier to form an idea of the large extent of a city so irregularly built by the number of the people, who are computed to be near a million ; and from the number of edifices devoted to the service of religion.

163
General
enumeration
of
churches,
chapels, &c.

Of these, beside St Paul's cathedral and the collegiate church at Westminster, here are 102 parish-churches, and 69 chapels, of the established religion : 21 French protestant chapels ; 11 chapels belonging to the Germans, Dutch, Danes, &c. ; 26 independent meetings ; 34 presbyterian meetings ; 20 baptist meetings ; 19 popish chapels, and meeting-houses for the use of foreign ambassadors and people of various sects ; and three Jews synagogues. So that there are 305 places devoted to religious worship in the compass of this vast pile of buildings, without reckoning the 21 out-parishes usually included in the bills of mortality, and a great number of methodist tabernacles.

164
Hospitals,
schools,
houses, &c.

There are also in and near this city 100 alms-houses, about 20 hospitals and infirmaries, 3 colleges, 10 public prisons, 15 flesh-markets ; one market for live cattle ; two other markets more particularly for herbs ; and 23 other markets for corn, coals, hay, &c. ; 15 inns of court, 27 public squares, besides those within single buildings, as the Temple, &c. ; 3 bridges, 55 halls for companies, 8 public schools, called free-schools ; and 131 charity-schools, which provide education for 5034 poor children ; 207 inns, 447 taverns, 551 coffee-houses, 5975 alehouses ; 1000 hackney-coaches ; 400 ditto chairs ; 7000 streets, lanes, courts, and alleys, and 150,000 dwelling-houses, containing, as has been already observed, about 1,000,000 inhabitants ;

165
Number of
inhabitants.

who, according to a moderate estimate, are supposed to consume the following provisions weekly :

London

	L.	s.	d.
1000 Bullocks, at 6l. a-piece	6000	0	0
6000 Sheep, at 12s. a-piece	3600	0	0
2000 Calves, at 1l. 4s. a-piece	2400	0	0
3000 Lambs, at 8s. a-piece, for six months	1200	0	0
1500 Hogs in pork and bacon, at 20s. for six months	1500	0	0
2000 Pigs, at 2s. 6d. a-piece	250	0	0
1000 Turkeys, at 3s. 6d. a-piece, for six months	175	0	0
1000 Geese, at 2s. 6d. a-piece, for six months	125	0	0
2000 Capons, at 1s. 8d. a-piece	166	13	2
500 Dozens of Chickens at 9s. per dozen	225	0	0
4300 Ducks, at 9d. a-piece	161	5	4
1500 Dozen of rabbits, at 7s. per dozen, for eight months	525	0	0
2000 Dozen of pigeons, at 2s. per dozen, for eight months	200	0	0
700 Dozen of wild-fowl, of several sorts, for six months	250	0	0
In salt and fresh fish, at 1d. a-day, for half a million of people for one week	14,583	6	8
In bread of all sorts, white and brown at 1d. a-day, for one million of people for a week	29,166	13	4
300 Tons of wine, of all sorts, at 50l. a ton, one sort with another, for one week	15,000	0	0
In milk, butter, cheese, &c. at 1d. a-day, for a million of people for a week	29,166	13	4
In fruit of all sorts, at one farthing a-day, for a million of people for a week	7291	13	4
In eggs of hens, ducks, geese, &c. at half a farthing a-day, for a million of people for a week	13645	16	4
In beer and ale, strong and small, at 2d. a-day, for a million of people for a week	58,333	6	8
In sugar, plums, and spice, and all sorts of grocery, at a halfpenny a-day, for a million of people for a week	14,583	6	8
In wheat-flour, for pies and puddings, oatmeal and rice, &c. at half a farthing a-day, for a million of people for a week	3645	16	8
In salt, oil, vinegar, capers, olives, and other sauces, at half a farthing a-day, for a million of people for a week	3645	16	8
In roots and herbs of all sorts, both for food and physic, at half a farthing a-day, for a million of people for a week	3645	11	8
In sea-coal, charcoal, candles, and firewood, of all sorts, at 1d. a-day, for a million of people for a week	29,166	13	4

166

London.
Londonderry.

In paper of all sorts (a great quantity being used in printing) quills, pens, ink, and wax, at a farthing a-day, for amillion of people for a week

In tobacco, pipes, and snuff, at half a farthing a-day, for a million of people for a week

In cloathing, as linen and woollen, for men, women, and children, shoes, stockings, &c. at 3s. 6d. per week, for a million of people for a week

Expences for horse-meat, in hay, oats, beans, 1000 load of hay a-week, at 40s. a-load, comes to 2000l. in oats and beans the like value, 2000l. which is in all, for one week

Cyder, mum, brandy, strong waters, coffee, chocolate, tea, &c. at 1d. a-day, for a million of people for one week

The common firing is pit-coal, commonly called *fire-coal*, of which there are consumed upwards of 766,880 chaldrons every year. The annual consumption of oil in London and Westminster for lamps, amounts to 400,000l. In 1787, the quantity of porter brewed in London for home-consumption and foreign exportation, amounted to 1,176,856 barrels.

This great and populous city is happily supplied with abundance of fresh water from the Thames and the New River; which is not only of inconceivable service to every family, but by means of fire-plugs every where dispersed, the keys of which are deposited with the parish-officers, the city is in a great measure secured from the spreading of fire; for these plugs are no sooner opened, than there are vast quantities of water to supply the engines. This plenty of water has been attended with another advantage, it has given rise to several companies, who insure houses and goods from fire; an advantage that is not to be met with in any other nation on earth: the premium is small, and the recovery in case of loss is easy and certain. Every one of these offices keep a set of men in pay, who are ready at all hours to give their assistance in case of fire; and who are on all occasions extremely bold, dexterous, and diligent: but though all their labours should prove unsuccessful, the person who suffers by this devouring element has the comfort that must arise from a certainty of being paid the value (upon oath) of what he has insured.

The places for diversion are, Vauxhall, Ranelagh-gardens, the two play-houses, one of them rebuilding, the Pantheon lately burnt down; and the little theatre in the Hay-market, with Sadlers-wells, Hughes's Circus, and Aisle's Royal-Grove, &c. The finest repositories of rarities and natural history, are Sir Hans Sloane's, in the British Museum, already described; and another collected by the late Sir Ashton Lever, now the private property of Mr Parkinson, and deposited in proper apartments for public inspection, near the fourth end of Blackfriars bridge.

LONDONDERRY, or COLERAINE, a county of Ireland, in the province of Ulster. It is bounded on the fourth and south-west by the county of Tyrone; N^o 187.

by Antrim on the east, from which it is parted by the river Bann; by Donegal on the west; and that county and the Deucalidonian ocean on the north. Its greatest length is about 36 miles, its breadth 30, containing about 251,510 acres. The bogs and heaths of this county are manured with sea-shells, as those of Donegal. Like that, too, it is pretty champaign, and not unfruitful. It is particularly noted for a very clear river called the *Bann*, abounding with salmon, a fish said to delight in limpid streams. This river, to distinguish it from a lesser of the same name, is called the *Greater or Lower Bann*. In order to cultivate, settle, and civilize this county, king James I. granted it, by letters-patent, to a society, by the name of the *Governor and Assistants at London of the new plantation of Ulster in the realm of Ireland*. It contains six baronies; and, besides the two knights of the shire, sends to parliament two members for the city of Londonderry, and two each for Coleraine and Newton-Lisnawady or Lamneevady.

LONDONDERRY, or Derry, the capital of the county, and the see of a bishop, stands at the bottom of Lough-Foyle. This city has a very good port, to which ships of the greatest burden have access, and a considerable trade. It will be ever famous for the gallantry and perseverance with which it defended itself in three memorable sieges, in defiance of the greatest hardships and discouragements, namely, 1st, In 1641, when the rebels could not reduce it either by fraud or force. 2dly, In 1649, when it was besieged by the Lord Ardes, and reduced almost to extremity by famine, till at last relieved by troops sent from England. 3dly, When it held out against the French and Irish from the 7th of December 1688 to the last day of July 1689, though it was neither well fortified nor provided with a garrison or stores of provision and ammunition, and hardly any attempt made to relieve it during so long a time. Though the city is 20 miles up the river, yet very large ships can come up to the quay, where there are four or five fathoms of water. It is now well fortified with a strong wall, besides outworks; and along the banks of the river are several castles and a fort. This city is of no great antiquity, having been built and planted in the reign of James I. by a colony sent by the society abovementioned. The trade of the town is very considerable, having not only a large share in the herring-fishery, but sending ships also to the West-Indies, New-England, and Newfoundland, for which they are so advantageously situated, that a vessel bound from thence to America often arrives there before a London ship can get clear of the soundings, or arrive in the latitude of Londonderry. Tho' there are a great many shallows in Lough-Foyle, which serve it instead of a road; yet they are easily avoided, as there are deep channels between them. Those points called *Emilstone*, *Rystrhull*, or *Caldy-head*, which lie a little to the west of the mouth of the harbour, are counted the most northerly of Ireland, lying in lat. 55. 20. The inhabitants of this city are almost all Protestants. It gave title of *earl* and *baron* to a branch of the family of Pitt, which became extinct in 1764; but part of the title was revived in Robert Stewart, who was created Baron Londonderry in 1789. A late traveller says, "Derry is, per-

Long. haps, the cleanest, best built, and most beautifully situated town in Ireland; and, excepting Corke, as convenient as any for commerce, foreign and domestic." The lake almost furrounds it; and the whole ground-plot both of it and its liberties belongs to the 12 great companies of London. Great quantities of salmon, salted and barrelled, are exported from hence to America.

LONG, an epithet given to whatever exceeds the usual standard of length.

Long-Boat, the largest and strongest boat belonging to any ship. It is principally employed to carry great burdens, as anchors, cables, ballast, &c. See *Boat*.

LONG (Roger), D. D. master of Pembroke-hall in Cambridge, Lowndes's professor of astronomy in that university, rector of Cherryhinton in Huntingdonshire, and of Bradwell *juxta mare* in Essex, was author of a well-known and much approved treatise of astronomy, and the inventor of a remarkably curious astronomical machine, thus described by himself. "I have, in a room lately built in Pembroke-hall, erected a sphere of 18 feet diameter, wherein above 30 persons may fit conveniently; the entrance into it is over the fourth pole by six steps; the frame of the sphere consists of a number of iron meridians, not complete semicircles, the northern ends of which are screwed to a large round plate of brass, with an hole in the centre of it; thro' this hole, from a beam in the ceiling, comes the north pole, a round iron rod, about three inches long, and supports the upper parts of the sphere to its proper elevation for the latitude of Cambridge; the lower part of the sphere, so much of it as is invisible in England, is cut off; and the lower or southern ends of the meridians, or truncated semicircles, terminate on, and are screwed down to, a strong circle of oak, of about 13 feet diameter; which, when the sphere is put into motion, runs upon large rollers of lignum vitæ, in the manner that the tops of some windmills are made to turn round. Upon the iron meridians is fixed a zodiac of tin painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the constellations and stars traced: the Great and Little Bear and Draco are already painted in their places round the north pole; the rest of the constellations are proposed to follow: the whole is turned round with a small winch, with as little labour as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about 1000 pounds. When it is made use of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well supported by a frame of large timber." Thus far Dr Long, before this curious piece of mechanism was perfected. Since the above was written, the sphere has been completely finished; all the constellations and stars of the northern hemisphere, visible at Cambridge, are painted in their proper places upon plates of iron joined together, which form one concave surface. Dr Long published a Commencement Sermon 1728; and an answer to Dr Galley's pamphlet on Greek Accents; and died December 16th 1770, at the age of 91. As the materials for this article are scanty, we shall subjoin, from the Gentleman's Magazine †, a few traits of him, as delineated in 1769 by Mr Jones. "He is now in the 88th year of his age, and for his years vegete and

active. He was lately (in October) put in nomination for the office of vice-chancellor. He executed that trust once before, I think in the year 1737; a very ingenious person, and sometimes very facetious. At the public commencement in the year 1713, Dr Greene (master of Bennet college, and afterwards bishop of Ely) being then vice chancellor, Mr Long was pitched upon for the tripos-performance; it was witty and humorous, and has passed through divers editions. Some that remembered the delivery of it, told me, that in addressing the vice-chancellor (whom the university was usually styled *Mist Greene*), the tripos-orator, being a native of Norfolk, and assuming the Norfolk dialect, instead of saying, *Domine Vice-Cancellarie*, did very archly pronounce the words thus, *Domina Vice-Cancellaria*; which occasioned a general smile in that great auditory. His friend the late Mr Bonfoy of Ripton told me this little incident, 'That he and Dr Long walking together in Cambridge in a dully evening, and coming to a short *post* fixed in the pavement, which Mr B. in the midst of chat and inattention, took to be a *boy* standing in his way, he said in a hurry, 'Get out of my way, boy.' 'That *boy*, Sir,' said the Doctor very calmly and slyly, is a *poet-boy*, who turns out of his way for nobody.'—I could recollect several other ingenious repartees if there were occasion. One thing is remarkable, he never was a hale and hearty man, always of a tender and delicate constitution, yet took great care of it. His common drink water; he always dined with the fellows in the hall. Of late years he has left off eating flesh-meats: in the room thereof, puddings, vegetables, &c. sometimes a glass or two of wine."

LONGEVITY, length of life.

From the different longevities of men in the beginning of the world, after the flood, and in these ages, Mr Derham draws an argument for the interposition of a divine Providence.

Immediately after the creation, when the world was to be peopled by one man and one woman, the ordinary age was 900 and upwards.—Immediately after the flood, when there were three persons to stock the world, their age was cut shorter, and none of those patriarchs, but Shem, arrived at 500. In the second century we find none that reached 200; in the third, none but Terah that came to 200 years; the world, at least a part of it, by that time being so well peopled, that they had built cities, and were cantoned out into different nations.—By degrees, as the number of people increased, their *longevity* dwindled, till it came down at length to 70 or 80 years; and there it stood, and has continued to stand ever since the time of Moses.—This is found a good medium, and by means hereof the world is neither overstocked, nor kept too thin; but life and death keep a pretty equal pace.

That the common duration of man's life has been the same in all ages since the above period, is plain both from sacred and profane history. To pass by others, Plato lived to 81, and was accounted an old man: and the instances of *longevity* produced by Pliny L. vii. c. 48. as very extraordinary, may most of them be matched in modern histories.—In the following Tables are collected into one point of view the most memorable instances of long-lived persons of whose age

† For 1783, p. 983.

Longevity. we have any authentic records. The first and second gill; who inserted them, accompanied by a third, together with a number of useful observations, in the first volume of the Memoirs of the Manchester Literary Society.

William Walker, aged 112,	not mentioned above, who was a foldier at the battle of Edge-hill.		

If we look back to an early period of the Christian era, we shall find that Italy has been, at least about that time, peculiarly propitious to longevity. Lord Bacon observes that the year of our Lord 76, in the reign of Vespasian, was memorable; for in that year was a taxing which afforded the most authentic method of knowing the ages of men. From it, there were found in that part of Italy lying between the Apennine mountains and the river Po 124 persons who either equalled or exceeded 100 years of age, namely:

54 persons of 100 Years each.

Longevity. Mr Carew, in his survey of Cornwall, assures us, that it is no unusual thing with the inhabitants of that county to reach 90 years of age and upwards, and even to retain their strength of body and perfect use of their senses. Besides Brown, the Cornish beggar, who lived to 120, and one Polezew to 130 years of age, he remembered the decease of four persons in his own parish, the sum of whose years, taken collectively, amounted to 340. Now, although longevity evident-

ly prevails more in certain districts than in others, yet it is by no means confined to any particular nation or climate; nor are there wanting instances of it, in almost every quarter of the globe, as appears from the preceding as well as the subsequent Tables; which might have been considerably enlarged, had it appeared necessary; but we have only added, in the last, three recent instances that are peculiarly remarkable.

The

(a) This man, in 1789, at the age of 120, quitted his native hills, and from the summit of Mount Jura undertook a journey to Versailles, to behold and return thanks to the National Assembly for the vote which had freed him and his poor countrymen from the feudal yoke. In the early part of his life, he was a servant in the family of the prince de Beaumont. His memory continued good to the last day of his life; and the principal inconveniences which he felt from his great age were, that his sight was weakened, and the natural heat of his body was so diminished, that he shivered with cold in the middle of the dog-days if he was not sitting by a good fire. This old man was received in the body of the house by the National Assembly, indulged with a chair, and directed to keep on his hat lest he should catch cold if he was to sit uncovered. A collection was made for him by the members, which exceeded 500l. Sterling; but he lived not to return to Mount Jura. He was buried on Saturday the 31st of January 1790, with great funeral pomp, in the parish-church of St Eustace at Paris.

(s) He served as a private at the taking of Gibraltar in 1704.

(t) *Memoirs of the Life and gallant Exploits of the Old Highlander Serjeant Donald Macleod*, &c. published Jan. 1791, in the 103^d year of his age.—This old gentleman, for it appears that he really is a gentleman both by birth and by behaviour, was born in the year of the Revolution, in the parish of Bracadill, in the isle of Sky and county of Inverness, North Britain. He is a cadet of the family of Ulinish in Sky; and descended, through his mother, from Macdonald of Slate, the ancestor of the present Lord Macdonald. The earlier part of his life coincided with the famine of seven years in Scotland; which was so great as to suggest, even to the patriotic Mr Fletcher, the idea of the people selling themselves as slaves for immediate subsistence. He was bred in the midst of want and hardships, cold, hunger, and for the years of his apprenticeship with a mason and stone-cutter in Inverness, in incessant fatigue. He enlisted, when a boy, in the Scottish service, in the town of Perth, in the last year of the reign of King William. The regiment into which he enlisted

Longevity.

The Antediluvians are purposely omitted, as bearing too little reference to the present race of mortals, to afford any satisfactory conclusions; and as they have been already taken notice of in a separate article; (see ANTEDILUVIANS). As the improbable stories of some persons who have almost rivalled them in modern times, border too much upon the marvellous to find a place in these tables, the present examples are abundantly sufficient to prove, that longevity does not depend, so much as has been supposed, on any particular climate, situation, or occupation in life: for we see, that it often prevails in places where all these are extremely dissimilar; and it would, moreover, be very difficult, in the histories of the several persons above mentioned, to find any circumstance common to them all, except, perhaps, that of being born of healthy parents, and of being inured to daily labour, temperance, and simplicity of diet. Among the inferior ranks of mankind, therefore, rather than among the sons of ease and luxury, shall we find the most numerous instances of longevity; even frequently, when other external circumstances seem extremely unfavourable: as in the case of the poor sexton at Peterborough, who, notwithstanding his unpromising occupation among dead bodies, lived long enough to bury two crowned heads, and to survive two complete generations. The livelihood of Henry Jenkins and old Parre, is said to have consisted chiefly of the coarsest fare, as they depended on precarious alms. To which may be added the remarkable instance of Agnes Milbourne, who, after bringing forth a numerous offspring, and being obliged, through extreme indigence, to pass the latter part of her life in St Luke's workhouse, yet reached her 106th year in that fordid and unfriendly situation. The plain diet and invigorating employments of a country life are acknowledged on all hands to be highly conducive to health and longevity, while the luxury and refinements of large cities are allowed to be equally destructive to the human species; and this consideration alone, perhaps, more than

counterbalances all the boasted privileges of superior Longevity. elegance and civilization resulting from a city life.

From country villages, and not from crowded cities, have the preceding instances of longevity been chiefly supplied. Accordingly it appears, from the London bills of mortality, during a period of 30 years, viz. from the year 1728 to 1758, the sum of the deaths amounted to 750,322, and that, in all this prodigious number, only 242 persons survived the 100th year of their age! This overgrown metropolis is computed by Dr Price to contain a ninth part of the inhabitants of England, and to consume annually 7000 persons, who remove into it from the country every year, without increasing it. He moreover observes, that the number of inhabitants in England and Wales has diminished about one-fourth part since the Revolution; and so rapidly of late, that in 11 years, near 200,000 of our common people have been lost. If the calculation be just, however alarming it may appear in a national view, there is this consolation, when considered in a philosophical light, that without partial evil, there can be no general good; and that what a nation loses in the scale of population at one period, it gains at another; and thus probably, the average number of inhabitants on the surface of the globe continues at all times nearly the same. By this medium, the world is neither overstocked with inhabitants nor kept too thin, but life and death keep a tolerably equal pace. The inhabitants of this island, comparatively speaking, are but as the dust of the balance; yet instead of being diminished, we are assured by other writers, that within these 30 years they are greatly increased.

The desire of self-preservation, and of protracting the short span of life, is so intimately interwoven with our constitution, that it is justly esteemed one of the first principles of our nature, and, in spite even of pain and misery, seldom quits us to the last moments of our existence. It seems, therefore, to be no less our duty than our interest, to examine minutely into the

various

was the Scots Royals, commanded by the earl of Orkney. That old military corps, at that time, used bows and arrows as well as swords, and wore steel caps. He served in Germany and Flanders under the duke of Marlborough, under the duke of Argyle in the rebellion 1715, in the Highland Watch, or companies raised for enforcing the laws in the Highlands; in the same companies when, under the name of the 42d regiment, they were sent abroad to Flanders, to join the army under the duke of Cumberland; in the same regiment in Ireland, and on the breaking out of the French war, 1757, in America. From the 42d he was draughted to act as a drill sergeant in the 78th regiment, in which he served at the reduction of Louisbourg and Quebec: After this he became an out-pensioner of Chelsea Hospital. But such was the spirit of this brave and hardy veteran, that he served in 1761 as a volunteer in Germany under the marquis of Granby; and offered his services in the American war to Sir Henry Clinton; who, though he declined to employ the old man in the fatigues and dangers of war, treated him with great kindness, allowed him a liberal weekly pension out of his own pocket, and sent him home in a ship charged with dispatches to government.—The sergeant, “as his memory, according to the observation of his biographer, is impaired, does not pretend to make an exact enumeration of all his offspring: but he knows of 16 sons now living, 14 of whom are in the army and navy, besides daughters; the eldest of whom by his present wife is a mantuamaker in Newcastle.—His eldest son is now 83 years old, and the youngest only nine. Nor, in all probability, would this lad close the rear of his immediate progeny, if his present wife, the boy's mother, had not attained to the 49th year of her age.”—In his prime, he did not exceed five feet and seven inches. He is now inclined through age to five feet five inches. He has an interesting physiognomy expressive of sincerity, sensibility, and manly courage. His biographer very properly submits it to the consideration of the Polygraphic Society, whether they might not do a thing worthy of themselves and their ingenious art, if they should multiply likenesses of this living antiquity, and circulate them at an easy rate throughout Britain and Europe. They would thus gratify a very general curiosity; a curiosity not confined to the present age.

Longevity various means that have been considered as conducive to health and long life; and, if possible, to distinguish such circumstances as are essential to that great end from those which are merely accidental. But here it is much to be regretted, that an accurate history of the lives of all the remarkable persons in the above table, so far as relates to the diet, regimen, and the use of the non-naturals, has not been faithfully handed down to us; without which it is impossible to draw the necessary inferences. Is it not then a matter of astonishment, that historians and philosophers have hitherto paid so little attention to longevity? If the present imperfect list should excite others, of more leisure and better abilities, to undertake a full investigation of so interesting a subject, the inquiry might prove not only curious but highly useful to mankind. In order to furnish materials for a future history of longevity, the bills of mortality throughout the kingdom ought first to be revised, and put on a better footing, agreeable to the scheme of which Manchester and Chester have already given a specimen highly worthy of imitation. The plan, however, might be further improved with very little trouble, by adding a particular account of the diet and regimen of every person who dies at 80 years of age or upwards; and mentioning whether his parents were healthy, long-lived people, &c. An accurate register, thus established throughout the British dominions, would be productive of many important advantages to society, not only in a medical and philosophical, but also in a political and moral view.

All the circumstances that are most essentially necessary to life, may be compromised under the six following heads: 1. Air and climate; 2. Meat and drink; 3. Motion and rest; 4. The secretions and excretions; 5. Sleep and watching; 6. Affections of the mind.

These, though all perfectly natural to the constitution, have by writers been styled the non-naturals, by a strange perversion of language; and have been all copiously handled under that improper term. However, it may not be amiss to offer a few short observations on each, as they are so immediately connected with the present subject.

1. *Air, &c.* It has long been known that fresh air is more immediately necessary to life than food; for a man may live two or three days without the latter, but not many minutes without the former. The vivifying principle contained in the atmosphere, so essential to the support of flame, as well as animal life, concerning which authors have proposed so many conjectures, appears now to be nothing else but that pure dephlogisticated fluid lately discovered by that ingenious philosopher Dr Priestley. The common atmosphere may well be supposed to be more or less healthy in proportion as it abounds with this animating principle. As this exhales in copious streams from the green leaves of all kinds of vegetables, even from those of the most poisonous kind, may we not, in some measure, account why instances of longevity are so much more frequent in the country than in large cities; where the air, instead of partaking so largely of this salutary impregnation, is daily contaminated with noxious animal effluvia and phlogiston?

With respect to climate, various observations conspire to prove, that those regions which lie within the

temperate zones are best calculated to promote long life. Hence, perhaps, may be explained, why Italy has produced so many long lived, and why islands in general are more salutary than continents; of which Bermudas and some others afford examples. And it is a pleasing circumstance that our own island appears from the above table (notwithstanding the sudden vicissitudes to which it is liable) to contain far more instances of longevity than could well be imagined. The ingenious Mr Whitehurst assures us, from certain facts, that Englishmen are in general longer lived than North Americans; and that a British constitution will last longer, even in that climate, than a native one. But it must be allowed in general, that the human constitution is adapted to the peculiar state and temperature of each respective climate, so that no part of the habitable globe can be pronounced too hot or too cold for its inhabitants. Yet, in order to promote a friendly intercourse between the most remote regions, the Author of nature has wisely enabled the inhabitants to endure great and surprising changes of temperature with impunity.

2. *Foods and drink.* Though foods and drink of the most simple kinds are allowed to be the best calculated for supporting the body in health, yet it can hardly be doubted but variety may be safely indulged occasionally, provided men would restrain their appetites within the bounds of temperance; for bountiful Nature cannot be supposed to have poured forth such a rich profusion of provisions, merely to tantalize the human species, without attributing to her the part of a cruel step-dame, instead of that of the kind and indulgent parent. Besides, we find, that by the wonderful powers of the digestive organs, a variety of animal and vegetable substances, of very discordant principles, are happily assimilated into one bland homogeneous chyle; therefore it seems natural to distrust those cynical writers, who would rigidly confine mankind to one simple dish, and their drink to the mere water of the brook. Nature, it is true, has pointed out that mild insipid fluid as the universal diluent, and therefore most admirably adapted for our daily beverage. But experience has equally proved, that vinous and spirituous liquors, on certain occasions, are no less salutary and beneficial, whether it be to support strength against sickness or bodily fatigue, or to exhilarate the mind under the pressure of heavy misfortunes. But, alas! what Nature meant for innocent and useful cordials, to be used only occasionally, and according to the direction of reason, custom and caprice have, by degrees, rendered habitual to the human frame, and liable to the most enormous and destructive abuses. Hence it may be justly doubted, whether gluttony and intemperance have not depopulated the world more than even the sword, pestilence, and famine. True, therefore, is the old maxim, "*Modus utendi est veneno facit medicamentum, ex medicamento venenum.*"

3. and 4. *Motion and rest, sleep and watching.* It is allowed on all hands, that alternate motion and rest, and sleep and watching, are necessary conditions to health and longevity; and that they ought to be adapted to age, temperament, constitution, temperature of the climate, &c.; but the errors which mankind daily commit in these respects become a fruitful source of diseases. While some are bloated and relaxed with

Longevity
Longfoot

ease and indolence, others are emaciated, and become rigid through hard labour, watching, and fatigue

5. *Secretions and excretions.* Where the animal functions are duly performed, the secretions go on regularly; and the different evacuations so exactly correspond to the quantity of aliment taken in, in a given time, that the body is found to return daily to nearly the same weight. If any particular evacuation happen to be preternaturally diminished, some other evacuation is proportionally augmented, and the equilibrium is commonly preserved; but continued irregularities, in these important functions, cannot but terminate in disease.

6. *Affections of the mind.* The due regulation of the passions, perhaps, contributes more to health and longevity than that of any other of the non-naturals. The animating passions, such as joy, hope, love, &c. when kept within proper bounds, gently excite the nervous influence, promote an equable circulation, and are highly conducive to health; while the depressing affections, such as fear, grief, and despair, produce the contrary effect, and lay the foundation of the most formidable diseases.

From the light which history affords us, as well as from some instances in the above table, there is great reason to believe, that longevity is in a great measure hereditary; and that healthy long-lived parents would commonly transmit the same to their children, were it not for the frequent errors in the non-naturals, which so evidently tend to the abbreviation of human life.

Where is it, but from these causes, and the unnatural modes of living, that, of all the children which are born in the capital cities of Europe, nearly one half die in early infancy? To what else can we attribute this extraordinary mortality? Such an amazing proportion of premature deaths is a circumstance unheard of among savage nations, or among the young of other animals! In the earliest ages, we are informed, that human life was protracted to a very extraordinary length; yet how few persons, in these latter times, arrive at that period which nature seems to have designed! Man is by nature a field-animal, and seems destined to rise with the sun, and to spend a large portion of his time in the open air, to inure his body to robust exercises and the inclemency of the seasons, and to make a plain homely repast only when hunger dictates. But art has studiously defeated the kind intentions of nature; and by enervating him to all the blandishments of sense, has left him, alas! an easy victim to folly and caprice. To enumerate the various abuses which take place from the earliest infancy, and which are continued through the succeeding stages of modish life, would carry us far beyond our present intention. Suffice it to observe, that they prevail more particularly among people who are the most highly polished and refined. To compare their artificial mode of life with that of nature, or even with the long-livers in the lit, would probably afford a very striking contrast; and at the same time supply an additional reason why, in the very large cities, instances of longevity are so very rare.

LONGFORD, a county of Ireland, in the province of Leinster, bounded by the county of Leitrim and Caven on the north, Meath on the east and south, and Roscommon on the west. It contains 134,700

Irish plantation acres, 24 parishes, 6 baronies, and 4 boroughs; and returns 10 members to parliament. It is small, and much encumbered with bog, intermixed with a tolerable good soil; and is about 25 miles long and 15 broad.

LONGFORD, a town of Ireland, situated on the river Cromlin, in the county of Longford and province of Leinster, 64 miles from Dublin; which river falls a few miles below this place into the Shannon. It is a borough, post, market, and fair town; and returns two members to parliament; patron, Lord Longford. It gave title of earl to the family of Angier; of viscount, to the family of Micklethwaite; and now gives that of baron to the family of Packenham. Within a mile and a half of the town is a charter-school for above 40 children. This place has a barrack for a troop of horse. It is large and well built; and in a very early age an abbey was founded here, of which St Idus, one of St Patrick's disciples, was abbot. In the year 1400, a fine monastery was founded to the honour of the Virgin Mary, for Dominican friars, by O'Ferral prince of Annaly. This monastery being destroyed by fire, Pope Martin V. by a bull in the year 1429, granted an indulgence to all who should contribute to the rebuilding of it. In 1433, Pope Eugene IV. granted a bull to the same purpose; and in 1438 he granted another to the like effect. The church of this friary, now the parish-church, is in the diocese of Ardagh. The fairs are four in the year.

LONG-ISLAND, is an island of North America, belonging to the state of New-York, which is separated from the continent by a narrow channel. It extends from the city of New-York east 140 miles, terminating with Montauk point; and is not more than 10 miles in breadth on a medium. It is divided into three counties, King's, Queen's, and Suffolk. The south side of the island is flat land, of a light sandy soil, bordered on the sea-coast with large tracts of salt meadow, extending from the west point of the island to Southampton. This soil, however, is well calculated for raising grain, especially Indian corn. The north side of the island is hilly, and of a strong soil, adapted to the culture of grain, hay, and fruit. A ridge of hills extends from Jamaica to South-hold. Large herds of cattle feed upon Hempstead plain and on the salt marshes upon the south side of the island. Hempstead plain in Queen's county is a curiosity. It is 16 miles in length, east and west, and 7 or 8 miles wide. The soil is black, and to appearance rich and yet it was never known to have any natural growth, but a kind of wild grafs and a few shrubs. It is frequented by vast numbers of plover. Rye grows tolerably well on some parts of the plain. The most of it lies common for cattle, horses, and sheep. As there is nothing to impede the prospect in the whole length of this plain, it has a curious but tiresome effect upon the eye, not unlike that of the ocean. The island contains 30,863 inhabitants.

LONGIMETRY, the art of measuring lengths, both accessible and inaccessible. See GEOMETRY and TRIGONOMETRY.

LONGING, is a preternatural appetite in pregnant women, and in some sick persons when about to recover. It is called *pica*, from the bird of that name, which is said to be subject to the same disorder. The disorder

Longford
Longing.

Longinus.
Longinus.

confists of both a desire of unusual things to eat and drink, and in being soon tired of one and wanting another. It is called *malicia*, from *μαλινος*, "weakness." In pregnant women it is somewhat relieved by bleeding, and in about the fourth month of their pregnancy it leaves them. Chlorotic girls, and men who labour under suppressed hemorrhoids, are very subject to this complaint, and are relieved by promoting the respective evacuations. In general, whether this disorder is observed in pregnant women, in persons recovering from an acute fever, or in those who labour under obstructions of the natural evacuations, this craving of the appetite should be indulged.

LONGINICO, a town of Turkey in Europe, in the Morea, anciently called *Olympia*, famous for being the place where the Olympic games were celebrated, and for the temple of Jupiter Olympus, about a mile distant. It is now but a small place, seated on the river Alpheus, 10 miles from its mouth, and 50 south of Lepanto. E. Long. 22. 0. N. Lat. 37. 30.

LONGINUS (Dionysius), a celebrated Greek critic of the third century, was probably an Athenian. His father's name is unknown, but by his mother he was allied to the celebrated Plutarch. His youth was spent in travelling with his parents, which gave him an opportunity to increase his knowledge, and improve his mind. After his travels, he fixed his residence at Athens, and with the greatest assiduity applied to study. Here he published his Treatise on the Sublime; which raised his reputation to such a height, and gave the Athenians such an opinion of his judgment and taste, that they made him sovereign judge of all authors, and every thing was received and rejected by the public according to his decisions. He seems to have staid at Athens a long time; here he taught the academic philosophy, and among others had the famous Porphyry for his pupil. But it was at length his fortune to be drawn from Athens, and to mix in more active scenes; to train up young princes to virtue and glory; to guide the busy passions of the great to noble objects; to struggle for, and at last to die, in the cause of liberty. Zenobia, queen of the East, prevailed on him to undertake the education of her sons; and he soon gained an uncommon share in her esteem: she spent the vacant hours of her life in his conversation, and modelled her sentiments and conduct by his instructions. That prince was at war with Aurelian; and being defeated by him near Antioch, was compelled to shut herself up in Palmyra, her capital city. The emperor wrote her a letter, in which he ordered her to surrender; to which she returned an answer, drawn up by Longinus, which filled him with resentment. The emperor laid siege to the city; and the Palmyrians were at length obliged to open their gates and receive the conqueror. The Queen and Longinus endeavoured to fly into Persia; but were unhappily overtaken and made prisoners when they were on the point of crossing the Euphrates. The Queen, intimidated, weakly laid the blame of vindicating the liberty of her country on its true author; and the brave Longinus, to the disgrace of the conqueror, was carried away to immediate execution. The writings of Longinus were numerous, some on philosophical, but the greater part on critical subjects. Dr Pearce has collected the titles of 25 treatises, none of which, excepting that on the Sublime, have escaped

the depredations of time and barbarians. On this imperfect piece the great fame of Longinus is raised, who, as Pope expresses it—"is himself the great fublime he draws." The best edition of his works is that by Tollius, printed at Utrecht in 1694, *cum notis variorum*. It has been translated into English by Mr Smith.

LONGISSIMUS DORSI. See ANATOMY, Table of the Muscles.

LONGITUDE, in geography and navigation, is the distance of any place from another eastward or westward, counted in degrees upon the equator; but when the distance is reckoned by leagues or miles and not in degrees, or in degrees on the meridian, and not of the parallel of latitude, in which case it includes both latitude and longitude, it is called *departure*.

To find the longitude at sea, is a problem to which the attention of navigators and mathematicians has been drawn ever since navigation began to be improved.—The importance of this problem soon became well known, that, in 1598, Philip III. of Spain offered a reward of 1000 crowns for the solution; and his example was soon followed by the States General, who offered 10,000 florins. In 1714 an act was passed in the British parliament, empowering certain commissioners to make out a bill for a sum not exceeding 2000 l. for defraying the necessary expences of experiments for ascertaining this point; and likewise granting a reward to the person who made any progress in the solution, proportionable to the degree of accuracy with which the solution was performed: 10,000 l. was granted if the longitude should be determined to one degree of a great circle, or 60 geographical miles; 15,000 if to two thirds of that distance; and 20,000 if to the half the distance.

In consequence of these proffered rewards, innumerable attempts were made to discover this important secret. The first was that of John Morin professor of mathematics at Paris, who proposed it to Cardinal Richelieu; and though it was judged insufficient on account of the imperfection of the lunar tables, a pension of 2000 livres *per annum* was procured for him in 1645 by Cardinal Mazarine. Gemma Frisius had indeed, in 1530, projected a method of finding the longitude by means of watches, which at that time were newly invented: but the structure of these machines was then by far too imperfect to admit of any attempt; nor even in 1631, when Metius made an attempt to this purpose, were they advanced in any considerable degree. About the year 1664, Dr Hooke and Mr Huygens made a very great improvement in watchmaking, by the application of the pendulum spring. Dr Hooke having quarrelled with the ministry, no experiment was made with any of his machines; but many were made with those of Mr Huygens. One experiment, particularly, made by Major Holmes, in a voyage from the Coast of Guinea in 1665, answered so well, that Mr Huygens was encouraged to improve the structure of his watches; but it was found that the variations of heat and cold produced such alterations in the rate of going of the watch, that unless this could be remedied, the watches could be of little use in determining the longitude.

In 1714 Henry Sully, an Englishman, printed a small tract at Vienna upon the subject of watchmaking.

Longit.
mus.
Longitude.

making. Having afterwards removed to Paris, he applied himself to the improvement of time-keepers for the discovery of the longitude. He taught the famous Julian de Roy; and this gentleman, with his son, and M. Berthoud, are the only persons who, since the days of Sully, have turned their thoughts this way. But though experiments have been made at sea with some of their watches, it does not appear that they have been able to accomplish any thing of importance with regard to the main point. The first who succeeded in any considerable degree was Mr John Harrison; who, in 1726, produced a watch which went so exactly, that for ten years together it did not err above one second in a month. In 1736 it was tried in a voyage to Lisbon and back again, on board one of his Majesty's ships; during which it corrected an error of a degree and an half in the computation of the ship's reckoning. In consequence of this he received public encouragement to go on; and by the year 1761 had finished three time-keepers, each of them more accurate than the former. The last turned out so much to his satisfaction, that he now applied to the commissioners of longitude for leave to make an experiment with his watch in a voyage to the West Indies. Permission being granted, his son Mr William Harrison set out in his Majesty's ship the *Deptford* for Jamaica in the month of November 1761. This trial was attended with all imaginable success. The longitude of the island, as determined by the time-keeper, differed from that found by astronomical observations only one minute and a quarter of the equator; the longitudes of places seen by the way being also determined with great exactness. On the ship's return to England, it was found to have erred no more during the whole voyage than $1^{\circ} 54\frac{1}{2}'$ in time, which is little more than 28 miles in distance; which being within the limits prescribed by the act, the inventor claimed the whole £.20,000 offered by government. Objections to this, however, were soon started. Doubts were pretended about the real longitude of Jamaica, as well as the manner in which the time had been found both there and at Portsmouth. It was alleged also, that although the time-keeper happened to be right at Jamaica, and after its return to England, this was by no means a proof that it had always been so in the intermediate times; in consequence of which allegations, another trial was appointed in a voyage to Barbadoes. Precautions were now taken to obviate as many of these objections as possible. The commissioners sent out proper persons to make astronomical observations at that island; which, when compared with others in England, would ascertain beyond a doubt its true situation. In 1764 then, Mr Harrison junior set sail for Barbadoes; and the result of the experiment was, that the difference of longitude betwixt Portsmouth and Barbadoes was shown by the time-keeper to be $3^{\text{h}}. 55^{\text{m}}. 3^{\text{s}}$; and by astronomical observations to be $3^{\text{h}}. 54^{\text{m}}. 20^{\text{s}}$; the error being now only $43''$ of time, or $10^{\circ} 45'$ of longitude. In consequence of this and the former trials, Mr Harrison received one half of the reward promised, upon making a discovery of the principles upon which his time-keepers were constructed. He was likewise promised the other half of the reward as soon as time-keepers should be constructed by other artists which should answer the purpose as

well as those of Mr Harrison himself. At this time he delivered up all his time-keepers, the last of which was sent to Greenwich to be tried by Mr Nevil Maskelyne the astronomer-royal. On trial, however, it was found to go with much less regularity than had been expected; but Mr Harrison attributed this to his having made some experiments with it which he had not time to finish when he was ordered to deliver up the watch. Soon after this, an agreement was made by the commissioners with Mr Kendall to construct a watch upon Mr Harrison's principles; and this upon trial was found to answer the purpose even better than any that Harrison himself had constructed. This watch was sent out with Captain Cook in 1772; and during all the time of his voyage round the world in 1772, 1773, 1774, and 1775, never erred quite $14\frac{1}{2}$ seconds per day: in consequence of which, the house of commons, in 1774, ordered the other £.10,000 to be paid to Mr Harrison. Still greater accuracy, however, has been attained. A watch was lately constructed by Mr Arnold, which, during a trial of 13 months, from February 1779 to February 1780, varied no more than 6.69 during any two days; and the greatest difference between its rates of going on any day and the next to it was .11." The greatest error it would have committed therefore in the longitude during any single day would have been very little more than one minute of longitude; and thus might the longitude be determined with as great exactness as the latitude generally can.—This watch, however, has not yet been tried at sea.

Thus the method of constructing time-keepers for discovering the longitude seems to be brought to as great a degree of perfection as can well be expected. Still, however, as these watches are subject to accidents, and may thus alter the rate of their going without any possibility of a discovery, it is necessary that some other method should be fallen upon, in order to correct from time to time those errors which may arise either from the natural going of the watch, or from any accident which may happen to it. Methods of this kind are all founded upon celestial observations of some kind or other; and for these methods, or even for an improvement in time-keepers, rewards are still held out by government. After the discoveries made by Mr Harrison, the act concerning the longitude was repealed, excepting so much of it as related to the constructing, printing, publishing, &c. of nautical almanacks and other useful tables. It was enacted also, that any person who shall discover a method for finding the longitude by means of a time-keeper, the principles of which have not hitherto been made public, shall be intitled to a reward of £.5000, if, after certain trials made by the commissioners, the said method shall enable a ship to keep her longitude during a voyage of six months within 60 geographical miles or a degree of a great circle. If the ship keeps her longitude within 40 geographical miles for that time, the inventor is intitled to a reward of £.7500, and to £.10,000 if the longitude is kept within half a degree. If the method is by improved astronomical tables, the author is intitled to £.5000 when they show the distance of the moon from the sun and stars within 15 seconds of a degree, answering to about 7 minutes of longitude, after allowing half a degree for errors

Longitude. errors of observation, and under certain restrictions, and after comparison with astronomical observations for a period of $18\frac{1}{2}$ years, during which the lunar irregularities are supposed to be completed. The same rewards are offered to the person who shall with the like accuracy discover any other method of finding the longitude.

These methods require celestial observations; and any of the phenomena, such as the different apparent places of stars with regard to the moon, the beginning and ending of eclipses, &c. will answer the purpose: only it is absolutely necessary that some variation should be perceptible in the phenomenon in the space of two minutes; for even this short space of time will produce an error of 30 miles in longitude. The most proper phenomena therefore for determining the longitude in this manner are the eclipses of Jupiter's satellites. Tables of their motions have been constructed, and carefully corrected from time to time, as the mutual attractions of these bodies are found greatly to disturb the regularity of their motions. The difficulty here, however, is to observe these eclipses at sea; and this difficulty has been found so great, that no person seems able to surmount it. The difficulty arises from the violent agitation of a ship in the ocean, for which no adequate remedy has ever yet been found, nor probably will ever be found. Mr Christopher Irwin indeed invented a machine which he called a *marine chair*, with a view to prevent the effects of this agitation; but on trying it in a voyage to Barbadoes, it was found to be totally useless.

A whimsical method of finding the longitude was proposed by Messrs Whiston and Ditton from the report and flash of great guns. The motion of sound is known to be nearly equal, from whatever body it proceeds or whatever be the medium. Supposing therefore a mortar to be fired at any place the longitude of which is known, the difference between the moment that the flash is seen and the report heard will give the distance between the two places; whence, if we know the latitudes of these places, their longitudes must also be known. If the exact time of the explosion be known at the place where it happens, the difference of time at the place where it is heard will likewise give the difference of longitude. Let us next suppose the mortar to be loaded with an iron shell filled with combustible matter, and fired perpendicularly upward into the air, the shell will be carried to the height of a mile, and will be seen at the distance of near 100; whence, supposing neither the flash of the mortar should be seen nor the report heard, still the longitude might be determined by the altitude of the shell above the horizon.

According to this plan, mortars were to be fired at certain times and at proper stations along all frequented coasts for the direction of mariners. This indeed might be of use, and in stormy weather might be a kind of improvement in light-houses, or a proper addition to them; but with regard to the determination of longitudes, is evidently ridiculous.

We shall now proceed to give some practical directions for finding the longitude at sea by proper celestial observations; exclusive of those from Jupiter's satellites, which, for reasons just mentioned, cannot be practised at sea. In the first place, however, it will be

Longitude. necessary to point out some of those difficulties which stand in the way, and which render even this method of finding the longitude precarious and uncertain. These lie principally in the reduction of the observations of the heavenly bodies made on the surface of the earth to similar observations supposed to be made at the centre; which is the only place where the celestial bodies appear in their proper situation. It is also very difficult to make proper allowances for the refraction of the atmosphere, by which all objects appear higher than they really are; and another difficulty arises from their parallaxes, which makes them, particularly the moon, appear lower than they would otherwise do, excepting when they are in the very zenith. It is also well known, that the nearer the horizon any celestial body is, the greater its parallax will be; and as the parallax and refraction act in opposite ways to one another, the former depressing and the latter raising the object, it is plain, that great difficulties must arise from this circumstance. The sun, for instance, whose parallax is less than the refraction, must always appear higher than he really is; but the moon, whose parallax is greater than her refraction, must always appear lower.

To render observations of the celestial bodies more easy, the commissioners of longitude have caused an Ephemeris or Nautical Almanack to be published annually, containing every requisite for solving this important problem which can be put into the form of tables. But whatever may be done in this way, it will be necessary to make the necessary preparations concerning the dip of the horizon, the refraction, semi-diameters, parallax, &c. in order to reduce the apparent to the true altitudes and distances; for which we shall here subjoin two general rules.

The principal observation for finding the longitude at sea is that of the moon from the sun, or from some remarkable star near the zodiac. To do this, the operator must be furnished with a watch which can be depended upon for keeping time within a minute for six hours; and with a good Hadley's quadrant, or, which is preferable, a sextant; and this last instrument will still be more fit for the purpose if it be furnished with a screw for moving the index gradually; likewise an additional dark glass, but not so dark as the common kind, for taking off the glare of the moon's light in observing her distance from a star. A small telescope, which may magnify three or four times, is also necessary to render the contact of a star with the moon's limb more discernible. A magnifying glass of $1\frac{1}{2}$ or 2 inches focus will likewise assist the operator in reading off his observations with the greater facility.

1. *To make the observation.* Having examined and adjusted his instrument as well as possible, the observer is next to proceed in the following manner: If the distance of the moon from the sun is to be observed, turn down one of the screens; look at the moon directly through the transparent part of the horizon-glass; and keeping her in view, gently move the index till the sun's image be brought into the silvered part of that glass. Bring the nearest limbs of both objects into contact, and let the quadrant librate a little on the lunar ray; by which means the sun will appear to rise and fall by the side of the moon; in which motion the nearest limbs must be made to touch one another exactly by moving the index. The ob-

Longitude. servation is then made; and the division coinciding with that on the Vernier scale, will show the distance of the nearest limbs of the objects.

When the distance of the moon from a star is to be observed when the moon is very bright, turn down the lightest screen, or use a dark glass lighter than the screens, and designed for this particular purpose; look at the star directly through the transparent part of the horizon-glass; and keeping it there, move the index till the moon's image is brought into the silvered part of the same glass. Make the quadrant librate gently on the star's ray, and the moon will appear to rise and fall by the star: move the index between the librations, until the moon's enlightened limb is exactly touched by the star, and then the observation is made. In these operations, the plane of the quadrant must always pass through the two objects, the distance of which is to be observed; and for this purpose it must be placed in various positions according to the situation of the objects, which will soon be rendered easy by practice.

The observation being made, somebody at the very instant that the operator calls must observe by the watch the exact hour, minute, and quarter minute, if there be no second hand, in order to find the apparent time; and at the same instant, or as quick as possible, two assistants must take the altitudes of those objects the distance of which is observed; after which, the observations necessary for finding the longitude are completed.

The ephemeris shows the moon's distance from the sun, and likewise from proper stars, to every three hours of apparent time for the meridian of Greenwich; and that the greater number of opportunities of observing this luminary may be given, her distance is generally set down from at least one object on each side of her. Her distance from the sun is set down while it is between 40 and 120 degrees; so that, by means of a sextant, it may be observed for two or three days after her first and before her last quarter. When the moon is between 40 and 90 degrees from the sun, her distance is set down both from the sun and from a star on the contrary side; and, lastly, when the distance is above 120 degrees, the distance is set down from two stars, one on each side of her. The distance of the moon from objects on the east side of her is found in the ephemeris in the 8th and 9th pages of the month; and her distance from objects on the west is found in the 10th and 11th pages of the month.

When the ephemeris is used, the distance of the moon must only be observed from those stars the distance of which is set down there; and these afford a ready means of knowing the star from which her distance ought to be observed. The observer has then nothing more to do than to set his index to the distance roughly computed at the apparent time, estimated nearly for the meridian at Greenwich; after which he is to look to the east or west of the moon, according as the distance of the star is found in the 8th or 9th, or in the 10th or 11th, pages of the month; and having found the moon upon the horizon-glass, the star will easily be found by sweeping with the quadrant to the right or left, provided the air be clear and the star be in the line of the moon's shortest axis produced. The time at Greenwich is estimated by turning into time the supposed longitude

from that place, and adding it to the apparent time at *Longitude.* the ship, or subtracting it from it as occasion requires. The distance of the moon from the sun, or a star, is roughly found at this time, by saying, As 180 minutes (the number contained in three hours) is to the difference in minutes between this nearly estimated time and the next preceding time set down in the ephemeris; so is the difference in minutes between the distances in the ephemeris for the next preceding and next following times, to a number of minutes; which being added to the next preceding distance, or subtracted from it, according as it is increasing or decreasing, will give the distance nearly at the time the observation is to be made, and to which the index must be set.

An easier method of finding the angular distance is by bringing the objects nearly into contact in the common way, and then fixing the index tight to a certain degree and minute; waiting until the objects are nearly in contact, giving notice to the assistants to get ready with the altitudes, and when the objects are exactly in contact to call for the altitudes and the exact time by the watch. The observer may then prepare for taking another distance, by setting his index three or four minutes backwards or forwards, as the objects happen to be receding from or approaching to each other; thus proceeding to take the distance, altitudes, and time by the watch, as before. Thus the observer may take as many distances as he thinks proper; but four at the distance of three minutes, or three at the distance of four minutes, will at all times be sufficient. Thus not only the eye of the observer will be less fatigued, but he will likewise be enabled to manage his instrument with much greater facility in every direction, a vertical one only excepted. If in taking the distances the middle one can be taken at any even division on the arch, such as a degree, or a degree and 20 or 40 minutes, that distance will be independent of the Nonius division, and consequently free of those errors which frequently arise from the inequality of that division in several parts of the graduated arch. The observation ought always to be made about two hours before or after noon; and the true time may be found by the altitude of the sun taken at the precise time of the distance. If three distances are taken, then find the time by the altitude corresponding with the middle distance; and thus the observation will be secured from any error arising from the irregularity of the going of the watch. As the time, however, found by the altitude of a star cannot be depended upon, because of the uncertainty of the horizon in the night, the best way of determining the time for a night observation will be by two altitudes of the sun; one taken on the preceding afternoon, before he is within six degrees of the horizon; and the other on the next morning, when he is more than six degrees high. It must be observed, however, that in order to follow these directions, it is necessary that the atmosphere should be pretty free from clouds; otherwise the observer must take the observations at such times as he can best obtain them.

2. To reduce the observed Distance of the Sun or a Star from the moon to the true Distance. 1. Turn the longitude into time, and add it to the time at the ship if the longitude be west, but subtract it if it be east, which

which will give the supposed time at Greenwich; and this we may call *reduced time*. 2. Find the nearest noon or midnight both before and after the reduced time in the seventh page of the month in the ephemeris. 3. Take out the moon's semidiameter and horizontal parallaxes corresponding to these noons and midnights, and find their differences. Then say, As 12 hours is to the moon's semidiameter in 12 hours, so is the reduced time to a number of seconds; which, either added to or subtracted from the moon's semidiameter at the noon or midnight just mentioned, according as it is increasing or decreasing, will give her apparent semidiameter; to which add the correction from Table VIII. of the ephemeris, and the sum will be her true semidiameter at the reduced time. And as 12 hours is to the difference of the moon's horizontal parallax in 12 hours, so is the reduced time to a fourth number; which, being added to or subtracted from the moon's horizontal parallax at the noon or midnight before the reduced time, according as it is increasing or decreasing, the sum or difference will be the moon's horizontal parallax at the reduced time. 4. If the reduced time be nearly any even part of 12 hours, viz $\frac{1}{2}$ th, $\frac{1}{4}$ th, &c. these parts of the difference may be taken, and either added or subtracted according to the directions already given, without being at the trouble of working by the rule of proportion. 5. To the observed altitude of the sun's lower limb add the difference betwixt his semidiameter and dip; and that sum will be his apparent altitude. 6. From the sun's refraction take his parallax in altitude, and the remainder will be the correction of the sun's altitude. 7. From the star's observed altitude take the dip of the horizon, and the remainder will be the apparent altitude. 8. The refraction of a star will be the correction of its altitude. 9. Take the difference between the moon's semidiameter and dip, and add it to the observed altitude if her lower limb was taken, or subtract it if her upper limb was taken; and the sum or difference will be the apparent altitude of her centre. 10. From the proportional logarithm of the moon's horizontal parallax, taken out of the nautical almanack (increasing its index by 10), take the logarithmic cosine of the moon's apparent altitude, the remainder will be the proportional logarithm of her parallax in altitude; from which take her refraction, and the remainder will be the correction of the moon's altitude. 11. To the observed distance of the moon from a star add her semidiameter if the nearest limb be taken, but subtract it if the farthest limb was taken, and the sum or difference will be the apparent distance. 12. To the observed distance of the sun and moon add both their semidiameters, and the sum will be the apparent distance of their centres.

3. To find the true Distance of the Objects, having their apparent Altitudes and Distances. 1. To the proportional logarithm of the correction of the sun or star's altitude, add the logarithmic cosine of the sun or star's apparent altitude; the logarithmic sine of the apparent distance of the moon from the sun or star; and the logarithmic co-secant of the moon's apparent altitude. The sum of these, rejecting 30 from the index, will be the proportional logarithm of the first angle. 2. To the proportional logarithm of the correction of the sun or star's altitude, add the loga-

rithmic co-tangent of the sun or star's apparent altitude, and the logarithmic tangent of the apparent distance of the moon from the sun or star. The sum of these, rejecting 20 in the index, will be the proportional logarithm of the second angle. 3. Take the difference between the first and second angles, adding it to the apparent distance if it be less than 90, and the first angle be greater than the second; but subtracting it if the second be greater than the first. If the distance be greater than 90, the sum of the angles must be added to the apparent distance, which will give the distance corrected for the refraction of the sun or star. 4. To the proportional logarithm of the correction of the moon's altitude add the logarithmic cosine of her apparent altitude; and the logarithmic sine of the distance corrected for the sun or star's refraction, and the logarithmic co-secant of the sun or star's apparent altitude. The sum, rejecting 30 in the index, will be the proportional logarithm of the third angle. 5. To the proportional logarithm of the correction of the moon's apparent altitude, add the logarithmic co-tangent of her apparent altitude, and the tangent of the distance corrected for the sun or star's refraction; their sum, rejecting 20 in the index, will be the proportional logarithm of the fourth angle. 6. Take the difference between the third and fourth angles, and subtract it from the distance corrected for the sun or star's refraction if less than 90, and the third angle be greater than the fourth; or add it to the distance if the fourth angle be greater than the third; but if the distance be more than 90, the sum of the angles must be subtracted from it, to give the distance corrected for the sun or star's refraction, and the principal effects of the moon's parallax. 7. In Table XX. of the ephemeris, look for the distance corrected for the sun and star's refraction, and the moon's parallax in the top column, and the correction of her altitude in the left-hand side column; take out the number of seconds that stand under the former, and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the correction of the moon's altitude in the left-hand side column; take out the number of seconds that stand under the former and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the principal effects of the moon's parallax in the left-hand side column, and take out the number of seconds. The difference between these two numbers must be added to the corrected distance if less than 90, but subtracted from it if greater; and the sum or difference will be the true distance.

4. To determine the Longitude after having obtained the true Distance. Look in the ephemeris among the distances of the objects for the computed distance betwixt the moon and the other object observed on the given day. If it be found there, the time at Greenwich will be at the top of the column; but if it falls between two distances in the ephemeris which stand immediately before and after it, and also the difference between the distance standing before and

Longitude the computed distance; then take the proportional logarithms of the first and second differences, and the difference between these two logarithms will be the proportional logarithm of a number of hours, minutes, and seconds; which being added to the time standing over the first distance, will give the true time at Greenwich. Or it may be found by saying, As the first difference is to three hours, so is the second difference to a proportional part of time; which being added as above directed, will give the time at Greenwich. The difference between Greenwich time and that at the ship, turned into longitude, will be that at the time the observations were made; and will be east if the time at the ship is greater, but west if it is less.

Having given these general directions, we shall next proceed to show some particular examples of finding the longitude at sea by all the different methods in which it is usually tried.

1. *To find the Longitude by Computation from the Ship's Course.*—Were it possible to keep an accurate account of the distance the ship has run, and to measure it exactly by the log [†] or any other means, then both latitude and longitude would easily be found by settling the ship's account to that time. For the course and distance being known, the difference of latitude and departure is readily found by the Traverse Table; and the difference of longitude being known, the true longitude and latitude will also be known. A variety of causes, however, concur to render this computation inaccurate; particularly the ship's continual deflection from the course set by her playing to the right and left round her centre of gravity; the unequal care of those at the helm, and the distance supposed to be sailed being erroneous, on account of stormy seas, unsteady winds, currents, &c. for which it seems impossible to make any allowance. The place of the ship, however, is judged of by finding the latitude every day, if possible, by observations; and if the latitude found by observation agrees with that by the reckoning, it is presumed that the ship's place is properly determined; but if they disagree, it is concluded that the account of the longitude stands in need of correction, as the latitude by observation is always to be depended upon.

Currents very often occasion errors in the computation of a ship's place. The causes of these in the great depths of the ocean are not well known, though many of the motions near the shore can be accounted for. It is supposed that some of those in the great oceans are owing to the tide following the moon, and a certain libration of the waters arising from thence; likewise that the unsettled nature of these currents may be owing to the changes in the moon's declination. In the torrid zone, however, a considerable current is occasioned by the trade-winds, the motion being constantly to the west, at the rate of eight or ten miles per day. At the extremities of the trade-winds or near the 30th degree of north or south latitude, the currents are probably compounded of this motion to the westward, and of one towards the equator; whence all ships sailing within these limits ought to allow a course each day for the current.

When the error is supposed to have been occasioned by a current, it ought if possible to be tried whether the case is so or not; or we must make a reasonable

estimate of its drift and course. Then with the setting and drift, as a course and distance, find the difference of latitude and departure; with which the dead reckoning is to be increased or diminished: and if the latitude thus corrected agrees with that by observation, the departure thus corrected may be safely taken as true, and thus the ship's place with regard to the longitude determined.

EXAM. Suppose a ship in 24 hours finds, by her dead reckoning, that she has made 96 miles of difference of latitude north and 38 miles of departure west; but by observation finds her difference of latitude 112, and on trial that there is a current which in 24 hours makes a difference of 16 miles latitude north and 10 miles of departure east: Required the ship's departure.

	miles.	Departure by } miles.
Diff. lat. by account	96 N.	account } 38 W.
Diff. lat. by current	16 N.	current } 10
True diff. lat.	112	28 W.

Here the dead reckoning corrected by the current gives the difference of latitude 112 miles, which is the same as that found by observation; whence the departure 28 is taken as the true one.

When the error is supposed to arise from the courses and distances, we must observe, that if the difference of latitude is much more than the departure, or the direct course has been within three points of the meridian, the error is most probably in the distance. But if the departure be much greater than the difference of latitude, or the direct course be within three points of the parallel, or more than five points from the meridian, the error is probably to be ascribed to the course. But if the courses in general are near the middle of the quadrant, the error may be either in the course, or in the distance, or both. This method admits of three cases.

1. When, by the dead reckoning, the difference of latitude is more than once and an half the departure; or when the course is less than three points: Find the course to the difference of latitude and departure. With this course and the meridional difference of latitude by observation, find the difference of longitude.

2. When the dead reckoning is more than once and an half the difference of latitude; or when the course is more than five points: Find the course and distance with the difference of latitude by observation, and departure by account; then with the co-middle latitude by observation, and departure by account, find the difference of longitude.

3. When the difference of latitude and departure by account is nearly equal, or the direct course is between three and five points of the meridian: Find the course with the difference of latitude and departure by account since the last observation. With this course and the difference of latitude by observation find another departure. Take half the sum of these departures for the true one. With the true departure and difference of latitude by observation, find the true course; then with the true course and meridional difference of latitude find the difference of longitude.

2. *To find the Longitude at Sea by a Variation-chart.*—

Longitude. Dr Halley having collected a great number of observations on the variation of the needle in many parts of the world; by that means was enabled to draw certain lines on Mercator's chart, showing the variation in all the places over which they passed in the year 1700, at which time he first published the chart; whence the longitude of those places might be found by the chart provided its latitude and variation was given. The rule is, Draw a parallel of latitude on the chart through the latitude found by observation; and the point where it cuts the curved line marked with the variation that was observed will be the ship's place.

EXAM. A ship finds by observation the latitude to be $18^{\circ} 20'$ north; and the variation of the compass to be 4° west. Required the ship's place.—Lay a ruler over $18^{\circ} 20'$ north parallel to the equator; and the point where its edge cuts the curve of 4° west variation gives the ship's place, which will be found in about $27^{\circ} 10'$ west from London.

This method of finding the longitude, however, is attended with two inconveniences. 1. That when the variation lines run east or west, or nearly so, it cannot be applied; though as this happens only in certain parts of the world, a variationⁿ chart may be of great use for the rest. Even in those places indeed where the variation curves do run east or west, they may be of considerable use in correcting the latitude when meridian observations cannot be had; which frequently happens on the northern coasts of America, the Western Ocean, and about Newfoundland; for if the variation can be found exactly, the east and west curve answering to it will show the latitude. But, 2. The variation itself is subject to continual change; whence a chart, though ever so perfect at first, must in time become totally useless; and hence the charts constructed by Dr Halley, though of great utility at their first publication, became at length almost entirely useless. A new one was published in 1746 by Messrs Mountaine and Dodson, which was so well received, that in 1756 they again drew variation lines for that year, and published a third chart the year following. They also presented to the Royal Society a curious paper concerning the variation of the magnetic needle, with a set of tables annexed, containing the result of more than 50,000 observations, in six periodical reviews from the year 1700 to 1756 inclusive, adapted to every five degrees of latitude and longitude in the more frequented oceans; all of which were published in the Philosophical Transactions for 1757.

3. *To find the Longitude by the Sun's Declination.*—Having made such observations on the sun as may enable us to find his declination at the place, take the difference between this computed declination and that shown at London by the ephemeris; from which take also the daily difference of declination at that time; then say, as the daily difference of declination is to the above found difference, so is 360 degrees to the difference of longitude. In this method, however, a small error in the declination will make a great one in longitude.

4. *To find the Longitude by the Moon's culminating.*—Seek in the ephemeris for the time of her coming to the meridian on the given day and on the day following; and take their difference; also take the difference betwixt the times of culminating on the same

day as found in the ephemeris, and as observed; then say, as the daily difference in the ephemeris is to the difference between the ephemeris and observation; so is 360 degrees to the difference of longitude. In this method also a small difference in the culmination will occasion a great one in the longitude.

5. *By Eclipses of the Moon.*—This is done much in the same manner as by the eclipses of Jupiter's satellites: For if, in two or more distant places where an eclipse of the moon is visible, we carefully observe the times of the beginning and ending, the number of digits eclipsed, or the time when the shadow touches some remarkable spot, or when it leaves any particular spot on the moon, the difference of the times when the observations were made will give the difference of longitude. Phenomena of this kind, however, occur too seldom to be of much use.

6. In the 76th volume of the Philosophical Transactions, Mr Edward Pigot gives a very particular account of his method of determining the longitude and latitude of York; in which he also recommends the method of determining the longitude of places by observations of the moon's transit over the meridian. The instruments used in his observations were a gridiron pendulum-clock, a two feet and an half reflector, an eighteen inch quadrant made by Mr Bird, and a transit instrument made by Mr Sisson.

By these instruments an observation was made, on the 10th of September 1783, of the occultation of a star of the ninth magnitude by the moon, during an eclipse of that planet, at York and Paris. Besides this, there were observations made of the immerfions of ν Aquarii and δ Piscium; the result of all which was, that between Greenwich and York the difference of meridians was $4^{\circ} 27'$.

In 1783, Mr Pigot informs us, that he thought of finding the difference of meridians by observing the meridian right ascensions of the moon's limb. This he thought had been quite original; but he found it afterwards in the Nautical Almanack for 1769, and in 1784 read a pamphlet on the same subject by the Abbé Toaldo; but still found that the great exactness of this method was not suspected; though he is convinced that it must soon be universally adopted in preference to that from the first satellite of Jupiter.

After giving a number of observations on the satellites of Jupiter, he concludes, that the exactness expected from observations, even on the first satellite, is much over-rated. "Among the various objections (says he), there is one I have often experienced, and which proceeds solely from the disposition of the eye, that of seeing more distinctly at one time than another. It may not be improper also to mention, that the observation I should have relied on as the best, that of Aug. 30. 1785, marked *excellent*, is one of those most distant from the truth."

After giving a number of observations on the eclipse of the moon Sept. 10. 1783, our author concludes, that the eclipses of the moon's spots are in general too much neglected, and that it might be relied upon much more were the following circumstances attended to: 1. To be particular in specifying the clearness of the sky. 2. To choose such spots as are well defined, and leave no hesitation as to the part eclipsed. 3. That every observer should use, as far as possible, telescopes equally

Longitude. equally powerful, or at least let the magnifying powers be the same. "A principal objection (says he) may still be urged, viz. the difficulty of distinguishing the true shadow from the penumbra. Was this obviated, I believe the results would be more exact than from Jupiter's first satellite: Undoubtedly the shadow appears better defined if magnified little; but I am much inclined to think, that, with high magnifying powers, there is greater certainty of choosing the same part of the shadow, which perhaps is more than a sufficient compensation for the loss of distinctness."

The following rule for meridian observations of the moon's limb is next laid down: "The increase of the moon's right ascension in twelve hours (or any given time found by computation), is to 12 hours as the increase of the moon's right ascension between two places found by observation is to the difference of meridians.

Example.

Nov. 30, 1782.

h. ' "			
13 12 57.62	Meridian transit of moon's	} By clock at Green- wich.	
	second limb		
13 13 29.08	Ditto of α Υ		
31.46	Difference of right ascension.		
13 14 8.05	Meridian transit of moon's	} By clock at York.	
	second limb		
13 14 30.13	Ditto of α Υ		
22.08	Difference at York.	} The clocks going nearly federal time, no cor- rection is re- quired.	
31.46	Difference at Greenwich.		
9.33	Increase of the moon's ap- parent right ascension be- tween Greenwich and York, by observation.		

141' in seconds of a degree, ditto, ditto.

The increase of the moon's right ascension for 12 hours, by computation, is 23,340 seconds; and 12 hours reduced into seconds is 43,200. Therefore, according to the rule stated above,

$23,340' : 43,200' : \text{diff. of merid.} = 261''$.

"These easy observations and short reduction (says Mr Pigott) are the whole of the business. Instead of computing the moon's right ascension for 12 hours, I have constantly taken it from the Nautical Almanacks, which give it sufficiently exact, provided some attention be paid to the increase or decrease of the moon's motion. Were the following circumstances attended to, the results would be undoubtedly much more exact.

"1. Compare the observations with the same made in several other places. 2. Let several and the same stars be observed at these places. 3. Such stars as are nearest in right ascension and declination to the moon are infinitely preferable. 4. It cannot be too strongly urged to get, as near as possible, an equal number of observations of each limb, to take a mean of each set, and then a mean of both means. This will in a great measure correct the error of telescopes and sight. 5. The adjustment of the telescopes to the eye of the observer before the observation is also very necessary,

as the sight is subject to vary. 6. A principal error proceeds from the observation of the moon's limb, which may be considerably lessened, if certain little round spots near each limb were also observed in settled observatories; in which case the libration of the moon will perhaps be a consideration. 7. When the difference of meridians, or of the latitudes of places, is very considerable, the change of the moon's diameter becomes an equation.

"Though such are the requisites to use this method with advantage, only one or two of them have been employed in the observations that I have reduced. Two-thirds of these observations had not even the same stars observed at Greenwich and York; and yet none of the results, except a doubtful one, differ 15' from the mean; therefore I think we may expect a still greater exactness, perhaps within 10' if the above particulars be attended to.

"When the same stars are not observed, it is necessary for the observers at both places to compute their right ascension from tables, in order to get the apparent right of ascension of the moon's limb. Though this is not so satisfactory as by actual observation, still the difference will be trifling, provided the star's right ascensions are accurately settled. I am also of opinion, that the same method can be put in practice by travellers with little trouble, and a transit instrument, constructed so as to fix up with facility in any place. It is not necessary, perhaps, that the instrument should be perfectly in the meridian for a few seconds of time, provided stars, nearly in the same parallel of declination with the moon, are observed; nay, I am inclined to think, that if the instrument deviates even a quarter or half a degree, or more, sufficient exactness can be attained; as a table might be computed, showing the moon's parallax and motion for such deviation; which last may easily be found by the well known method of observing stars whose difference of declination is considerable.

"As travellers very seldom meet with situations to observe stars near the pole, or find a proper object for determining the error of the line of collimation, I shall recommend the following method as original.—Having computed the apparent right ascension of four, six, or more stars, which have nearly the same parallel of declination, observe half of them with the instrument inverted, and the other half when in its right position. If the difference of right ascensions between each set by observation agrees with the computation, there is no error; but if they disagree, half that disagreement is the error of the line of collimation. The same observations may also serve to determine, whether the distance of the corresponding wires are equal. In case of necessity, each limb of the sun might be observed in the same manner, though probably with less precision. By a single trial I made above two years ago, the result was much more exact than I expected. Mayor's catalogue of stars will prove of great use to those that adopt the above method.—I am rather surprised that the immersions of known stars of the sixth and seventh magnitude, behind the dark limb of the moon, are not constantly observed in fixed observatories, as they would frequently be of great use."

Longitude. The annexed rule for finding the ship's place, with the miscellaneous observations on different methods, we have been favoured with by Mr John M'Lean of the Observatory, Edinburgh. The rule was examined and approved of by Sir Joseph Banks president of the Royal Society.

1. With regard to determining the ship's place by the help of the course and distance sailed, the following rule may be applied.—It will be found as expeditious as any of the common methods by the middle latitude or meridional parts; and is in some respects preferable, as the common tables of sines and tangents only are requisite in applying it.—Let a and b be the distances of two places from the same pole in degrees, or their complete latitudes; c the angle which a meridian makes with the rhumb line passing through the places; and L the angle formed by their meridians, or the difference of longitude in minutes: then A and B being the logarithmic tangents of $\frac{1}{2}a$ and $\frac{1}{2}b$, S the sine of C , and S the sine of $(C+1)$, we shall have the following equation $L = \frac{A+B}{S-S'} (A)$. Also, from a well known property of the rhumb line, we have the following equation:

$S+E=R+D$, where S is the logarithmic cosine of C , E the logarithm of the length of the rhumb-line, or distance, D the logarithm of the minute's difference of latitude, and R the logarithm of the radius.

By the help of these two equations, we shall have an easy solution of the several cases to which the middle latitude, or meridional parts, are commonly applied.

Example. A ship from a port, in latitude 56° N. sails SW. by W. till she arrives at the latitude of 40° N: Required the difference of longitude.

Here $a=34^{\circ}$, $b=50^{\circ}$, $c=56^{\circ}15'$, $A=9.48534$, $B=9.56107$, $S=9.199308$, $S'=9.198464$; therefore, $L = \frac{A+B}{S-S'} = \frac{757300}{844} = 897$ the minutes difference of longitude. Also, $S=9.74474$, $D=2.98227$; therefore $E=R+D-S=3.23753$, to which the natural number is 1728, the miles in the rhumb-line sailed over.

2. The common method of finding the difference of longitude made good upon several courses and distances, by means of the difference of latitude and departure made good upon the several courses, is not accurately true.

For example: If a ship should sail due south 600 miles, from a port in 60° north latitude, and then due west 600 miles, the difference of longitude found by the common methods of solution would be 1053; whereas the true difference of longitude is only 933, less than the former by 120 miles, which is more than $\frac{1}{5}$ of the whole. Indeed every considerable alteration in the course will produce a very sensible error in the difference of longitude. Though, when the several rhumb lines sailed over are nearly in the same direction, the error in longitude will be but small.

The reason of this will easily appear from the annexed figure, in which the ship is supposed to sail from Z to

A , along the rhumb lines ZB , BA ; for if the meridians PZ , $PkoeBL$ be drawn; and very near the latter other two meridians PhD , Pmn ; and likewise the parallels of latitude Bn , De , mo , hk ; then it is plain that De is greater than hk (for De is to hk as the sine of DP to the sine of hP): and since this is the case every where, the departure corresponding to the distance BZ and course BZC , will be greater than the departure to the distance oZ , and course oZC . And in the same manner, we prove that nB is greater than mo ; and consequently, the departure corresponding to the distance AB , and course ABL , is greater than the departure to the distance Ao , and course AoL : Wherefore, the sum of the two departures corresponding to the courses ABL and BZC , and to the distances AB and BZ , is greater than the departure corresponding to the distance AZ and course AZC : therefore the course answering to this sum as a departure, and CZ as a difference of latitude, (AC being the parallel of latitudes passing through A), will be greater than the true course AZC made good upon the whole. And hence the difference of longitude found by the common rules will be greater than the true difference of longitudes; and the error will be greater or less according as BA deviates more or less from the direction of BZ .

3. Of determining the ship's longitude by lunar observations.

Several rules for this purpose have been lately published, the principal object of which seems to have been to abbreviate the computations requisite for determining the true distance of the sun or a star from the moon's centre. This, however, should have certainly been less attended to than the investigation of a solution, in which considerable errors in the data may produce a small error in the required distance. When either of the luminaries has a small elevation, its altitude will be affected by the variable refractions of the atmosphere; likewise the altitude, as given by the quadrant, will be affected by the inaccuracy of the instrument, and the uncertainty necessarily attending all observations made.

Longitude. made at sea. The sum of these errors, when they all tend the same way, may be supposed to amount to at least one minute in altitude; which, in many cases, according to the common rules for computing the true distance, will produce an error of about 30 minutes in the longitude. Thus, in the example given by Monf. Callet, in the *Tables Portatives*, if we suppose an error of one minute in the sun's altitude, or call it $6^{\circ} 26' 34''$, instead of $6^{\circ} 27' 34''$; we shall find the alteration in distance according to his rule to be $54''$, producing an error of about 27 minutes in the longitude: for the angle at the sun will be found, in the spherical triangle whose sides are the complement of the sun's altitude, complement of the moon's altitude, and observed distance, to be about 26° ; and as radius is to the cosine of 26° , so is $60''$ the supposed error in altitude, to $54''$ the alteration in distance. Perhaps the only method of determining the distance, so as not to be affected by the errors of altitude, is that by first finding the angles at the sun and moon, and by the help of them the corrections of distance for parallax and refraction. The rule is as follows:

Add together the complement of the moon's apparent altitude, the complement of the sun's apparent altitude, and the apparent distance of centres; from half the sum of these subtract the complement of the sun's altitude, and add together the logarithmic co-secant of the complement of the moon's altitude, the logarithmic co-secant of the apparent distance of centres, the logarithmic sine of the half sum, and the logarithmic sine of the remainder; and half the sum of these four logarithms, after rejecting 20 from the index, is the logarithmic cosine of half the angle at the moon.

As radius is to the cosine of the angle at the moon; so is the difference between the moon's parallax and refraction in altitude to a correction of distance; which

is to be added to the apparent distance of centres Longitude. when the angle at the moon is obtuse; but to be subtracted when that angle is acute, in order to have the distance once corrected.

In the above formula, if the word *sun* be changed for *moon*, and *vice versa*, wherever these terms occur, we shall find a second correction of distance to be applied to the distance, once corrected by subtraction when the angle at the sun is obtuse, but by addition when that angle is acute, and the remainder or sum is the true distance nearly.

In applying this rule, it will be sufficient to use the complement, altitudes, and apparent distances of centres, true to the nearest minute only, as a small error in the angles at the sun and moon will very little affect the corrections of distances.

If D be the computed distance in seconds, d the difference between the moon's parallax and refraction in altitude, S the sine of the angle at the moon, and R the radius; then $\frac{d^2 S^2}{2DR}$ will be a third correction

of distance, to be added to the distance twice corrected: But it is plain, from the nature of this correction, that it may be always rejected, except when the distance D is very small, and the angle at the moon nearly equal to 90° .

This solution is likewise of use in finding the true distance of a star from the moon, by changing the word *sun* into *star*, and using the refraction of the star, instead of the difference between the refraction and parallax in altitude of the sun, in finding the second correction of distance.

Ex. Given the observed distance of a star from the centre of the moon, $50^{\circ} 8' 41''$; the moon's altitude, $55^{\circ} 58' 5''$; the star's altitude, $19^{\circ} 18' 5''$; and the moon's horizontal parallax, $1^{\circ} 0' 5''$: Required the true distance.

Cofec. — 0.02512	*'s co. alt. — 70° 42'	Cofec. — 0.25169
	☽'s co. alt. — 34 4	
Cofec. — 0.11479	obl. diff. — 50 9	Cofec. — 0.11479
	2) 154 55	
Sine — 9.98950	77 27	Sine — 9.98950
	Rem. 6 45	Sine — 9.07018
Sine — 9.83688	Rem. 43 23	2) 19.42616
2) 19.96629		Cofec. — 9.71308 — 58° 54'
Cofec. — 9.98314	15° 54'	2
	2	117 48 = ☽'s angle.
	31 48 = *'s angle.	
Rad. : Cofec. 117° 48' :	☽'s diff. parall. & refract. 1980'' :	923'' = 1st correct. of distance.
Rad. · Cofec. 31° 48' :	star's refract. 162'' :	138'' = 2d correct. of distance.

Here the first correction of distance is additive, since the angle at the moon is obtuse; and the second correction is also additive, since the angle at the star is acute: therefore their sum $923'' + 138'' = 1061'' = 17^{\circ} 41''$, being added to $50^{\circ} 8' 41''$, the apparent No 188.

distance of the star from the moon's centre, gives $50^{\circ} 26' 21''$ for the true distance of centres nearly; and $2 \times L (d + S) - L (2 L R + L 2 + L D) = L 8''$, which, being added to the distance twice corrected, gives $50^{\circ} 26' 29''$ for the true distance. By comparing

Longitude—ring this distance with the computed distances in the ephemeris, the time at Greenwich corresponding to that of observing the distance will be known; and the difference of those times being converted into degrees and minutes, at the rate of 15 degrees to the hour, will give the longitude of the place of observation; which will be east if the time at the place be greater than that at Greenwich, but west if it be less.

LONGITUDINAL, in general, denotes something placed lengthwise: thus some of the fibres in the vessels of the human body are placed longitudinally, others transversely or acroli.

LONGOBARDI. See **LANGOBARDI**.

LONGOMONTANUS (Christian), a learned astronomer, born in a village of Denmark in 1562. He was the son of a ploughman; and was obliged to suffer during his studies all the hardships to which he could be exposed, dividing his time, like the philosopher Ctesarchus, between the cultivation of the earth and the lessons he received from the minister of the place. At last, when he was 15, he stole away from his family, and went to Wiburg, where there was a college, in which he spent 11 year; and though he was obliged to earn a livelihood, he applied himself to study with such ardour, that among other science he learned the mathematics in great perfection. He afterwards went to Copenhagen; where the professors of that university in a short time conceived so high an opinion of him, that they recommended him to the celebrated Tycho Brahe. Longomontanus lived eight years with that famous astronomer, and wa. of great service to him in his observations and calculations. At length, being extremely desirous of obtaining a professor's chair in Denmark, Tycho Brahe consented, though with some difficulty, to deprive himself of his service; gave him a discharge, filled with the highest testimonies of his esteem; and furnished him with money for the expence of his long journey. He obtained a professorship of mathematics in the university of Copenhagen in 1605; and discharged the duty of it worthily till his death, which happened in 1617. He wrote many learned works; amused himself with endeavouring to square the circle, and pretended that he had made that discovery; but Dr John Pell, an English mathematician, attacked him warmly on that subject, and proved that he was mistaken.

LONGTOWN, a town of Cumberland, on the Scots borders, near the conflux of the Elk and Kirkfo, seven miles from Carlisle, and 313 miles from London; it has a market on Thursday, and a charity-school for 60 children, and two fairs in the year.

LONGUEVILLE, a town of France, in Upper Normandy, and in the territory of Caux, seated on the small river Lee, 17 miles north of Rouen. It has the title of a duchy. E. Long. 1. 10. N. Lat. 49. 46.

LONGWY, a town of France, on the frontiers of the duchy of Luxemburg, with a castle, divided into the old and new towns. This last was built and fortified by Louis XIV. It is seated on an eminence. E. Long. 5. 51. N. Lat. 40. 32.

LONGUS, a Greek poet, author of a book intitled *Novus*, or Pastoral, and a romance containing the loves of Daphnis and Chloe. Huettius, bishop of Avranches, speaks very advantageously of this work; but he censures the obscene touches with which it is

interperfed. None of the ancient authors mention him, so the time when he lived cannot be certainly fixed. There is an English translation of this author, which is ascribed to the late J. Craggs, Esq; secretary of state.

LONGICERA, **HONEYSUCKLE**, in botany: A genus of the monogynia order, belonging to the pentandria class of plants. The corolla is monopetalous and irregular; the berry polyfpermous, bilocular, and inferior.

Species. 1. The alpigena, or upright red-berried honeysuckle, rises with a shrubby, short, thick, upright stem, branching strong and erectly four or five feet high; largish, spear-shaped leaves, in pairs opposite; and from the sides of the branches many red flowers by two's on long footstalks, each succeeded by two red berries joined together at their base; it flowers in August, and the berries ripen in autumn. 2. The carulea, or blue-berried upright honeysuckle, rises with a shrubby upright stem, branching moderately three or four feet high, with many white flowers proceeding from the sides of the branches; appearing in May, and succeeded by blue berries joined together at their base. 3. The nigra, or black-berried upright honeysuckle, rises with a shrubby stem branching three or four feet high, with white flowers succeeded by single and distinct black-berries. 4. The tartarica, or Tartarian honeysuckle, rises with a shrubby upright stem, branching erectly three or four feet high; heart-shaped, opposite leaves, and whitish erect flowers succeeded by red berries, sometimes distinct, and sometimes double. 5. The diervilla, or yellow-flowered Arcadian honeysuckle, rises with shrubby upright stalks, branching erect to the height of three or four feet; the branches terminated by clusters of pale yellow flowers, appearing in May and June, and sometimes continuing till autumn; but rarely ripening seeds here. 6. The xylosteum, or fly honeysuckle rises with a strong shrubby stem, branching erect to the height of seven or eight feet; with erect white flowers proceeding from the sides of the branches; each succeeded by large double red berries, joined together at their base. The flowers appear in June, and the berries ripen in September. 7. The symphoricarpos, or shrubby St Peter's-wort, rises with a shrubby, rough stem, branching erect four or five feet high, with small greenish flowers appearing round the stalk in August. 8. The periclymenum, or common climbing honeysuckle, hath two principal varieties, viz. The English wild honeysuckle, or woodbine of our woods and hedges, and the Dutch or German honeysuckle. The former rises with shrubby, weak, very long slender stalks, and branches trailing on the ground, or climbing round any support; all terminated by oval imbricated heads, furnishing smallish flowers of white or red colours, and appearing from June or July till autumn. The Dutch honeysuckle rises with a shrubby declinated stalk, and long trailing purplish branches, terminated by oval imbricated heads, furnishing large beautiful red flowers of a fragrant odour, appearing in June and July. 9. The caprifolium, or Italian honeysuckle, rises with shrubby declinated stalks, sending out long slender trailing branches, terminated by verticillate or whorled bunches of close-fitting flowers, very fragrant, and white, red, and yellow colours. 10. The sempervirens, or evergreen trumpet-flowered honeysuckle,

Longicera.

Loom

Loom

fuckle, rises with a flurby declinated stalk, sending out long slender trailing branches, terminated by naked verticillate spikes, of long, unreflexed, deep scarlet flowers, very beautiful, but of little fragrance.

Culture. The most easy method of propagating these plants is by layers or cuttings, especially the latter; both of these readily emit roots, and form plants in one year fit for transplantation. Some sorts are also propagated by suckers and feed.

LONSDALE, or *Kirkby LONSDALE*, a town of Westmoreland, seated on the river Lon, in a pleasant and rich valley of the same name. It is a large well-built town, has a handsome church, and a fine stone-bridge over the river. It is well inhabited; and is the best town in the county except Kendal. It gives title of Earl to the Lowther family. W. Long. 2. 27. N. Lat. 54. 10.

LOO, a town of the United Provinces, in Guelderland, eight miles west of Deventer, where the prince of Orange has a fine palace. E. Long. 6. 0. N. Lat. 52. 18.

LOOF, the after part of a ship's bow; or that part of her side forward where the planks begin to be incurved into an arch as they approach the stem.

LOOF, or *Luff*. See **LUFF**.

LOOK-OUT, in the sea-language, a watchful attention to some important object or event which is expected to arise from the present situation of a ship, &c. It is principally used in navigation when there is a probability of danger from the real or supposed proximity of land, rocks, enemies, and, in short, whatever peril she may encounter through inattention, which might otherwise have been avoided by a prudent and necessary vigilance.

There is always a look-out kept on a ship's fore-castle at sea, to watch for any dangerous objects lying near her track, and to which she makes a gradual approach as the advances: the mate of the watch accordingly calls often from the quarter-deck, "Look out afore there!" to the persons appointed for this service.

LOOKING-GLASSES, are nothing but plain mirrors of glass; which, being impervious to the light, reflect the images of things placed before them. See the articles **MIRROR** and **OPTICS**.

For the casting, grinding, and polishing of looking-glasses, see the article **GLASS**.

For foliating of looking-glasses. See the article **FOLIATING**.

LOOL, in metallurgy, a vessel made to receive the washings of ores of metals. The heavier or more metalline part of the ores remain in the trough in which they are washed; the lighter and more earthy run off with the water, but settle in the lool.

LOOM, the weaver's frame; a machine whereby several distinct threads are woven into one piece.

Looms are of various structures, accommodated to the various kinds of materials to be woven, and the various manner of weaving them; viz. for woollens, silks, linens, cottons, cloths of gold: and other works, as tapestry, ribbands, stockings, &c. divers of which will be found under their proper heads. See **WEAVING**.

The weaver's loom-engine, otherwise called the Dutch loom-engine, was brought into use from Holland to London, in or about the year 1676.

Heir-Loom, in law. See **HEIR-LOOM**.

LOOM, at sea. If a ship appears big, when at a distance, they say she looms, or appears a great sail: the term is also used to denote the indistinct appearance of any other distant objects.

LOOM-gale, at sea, a gentle ealy gale of wind, in which a ship can carry her top-sails a trip.

LOOP, in the iron works, is a part of a fow or block of cast iron broken or melted off from the rest, and prepared for the forge or hammer. The usual method is, to break off the loop of about three quarters of a hundred weight. This loop they take up with their slinging-tongs, and beat it with iron sledges upon an iron plate near the fire, that so it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and a little water being drawn to make the hammer move but softly, it is beat very gently, and by this means the dross and foulness are forced off, and after this they draw more and more water by degrees, and beat it more and more till they bring it to a four-square mass, of about two feet long, which they call a bloom.

LOOPING, in metallurgy, a word used by the miners of some counties of England, to express the running together of the matter of an ore into a mass, in the roasting or first burning, intended only to calcine it so far as to make it fit for powdering. This accident, which gives the miners some trouble, is generally owing to the continuing the fire too long in this process.

LOOSE-STRIPE. See **LYSIMACHIA**.

LOOSA, in botany: A genus of the monogynia order, belonging to the polyandria class of plants. The calyx is pentaphyllous, superior; there are five sub-ovate, cucullated, and large petals; the nectarium consists of five leaves, gathered into a conical figure, each terminated by two filaments; the capsule is turbinate, unilocular, and trivalved at top; the seeds are very numerous; and there are three linear and longitudinal sinuses.

LOPES LE VEGA. See **VEGA**.

LOPEZ, or **INDIAN**, Root, in the materia medica.

The plant to which this article belongs is unknown. Neither the woody nor cortical part of the root has any remarkable sensible quality. A slight bitterness is perceptible; and it is recommended, like simarouba, in diarrhoeas even of the colliquative kind, in half-dram doses four times a-day. Little of this root has been brought to Europe: but some of those who have had an opportunity of employing it, speak in very high terms of the effects obtained from it.

LOPHIUS, **FISHING-FROG**, *Toad-fish*, or *Sea-devil*; a genus of the branchiostegious order of fishes, whose head is in size equal to all the rest of the body. There are three species; the most remarkable of which is the plicatorius, or common fishing-frog, an inhabitant of the British seas. This singular fish was known to the ancients by the name of *βατραχίς*, and *rana*; and to us by that of the *fishing-frog*, for it is of a figure resembling that animal in a tadpole state. Pliny takes notice of the artifice used by it to take its prey: *Eminentia sub oculis cornicula turbato limo exerit, affusillantes pisciculos attrahens, donec tam prope accedunt, ut assillat.* "It puts forth the slender horns it has beneath its eyes, enticing by that means the little fish to play round, till they come within reach, when it springs

Loom

Lophius

Lothius
||
Lord.

Lord.

on them." The fishing-frog grows to a large size, some being between four and five feet in length; and Mr Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The fishermen on that coast have a great regard for this fish, from a supposition that it is a great enemy to the dog-fish; and whenever they take it with their lines, let it at liberty.

It is a fish of very great deformity: the head is much bigger than the whole body; is round at the circumference, and flat above; the mouth of a prodigious wideness. The under jaw is much longer than the upper: the jaws are full of slender sharp teeth: in the roof of the mouth are two or three rows of the same: at the root of the tongue, opposite each other, are two bones of an elliptical form, thick set, with very strong sharp teeth. The nostrils do not appear externally, but in the upper part of the mouth are two large orifices that serve instead of them. On each side the upper-jaw are two sharp spines, and others are scattered about the upper part of the head. Immediately above the nose are two long tough filaments, and on the back three others; these are what Pliny calls *cornicula*, and says it makes use of to attract the little fish. They seem to be like lines flung out for that end. Along the edges of the head and body are a multitude of short fringed skins, placed at equal distances. The aperture to the gills is placed behind; each of these is very wide, so that some writers have imagined it to be a receptacle for the young in time of danger. The body grows slender near the tail, the end of which is quite even. The colour of the upper part of this fish is dusky, the lower part white; the skin smooth.

LORANTHUS, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 48th order, *Aggrogata*. The germen is inferior; there is no calyx; the corolla is sixfold and revolved; the stamina are at the tops of the petals; the berry is monospermous. There is only one species, a native of America, discovered by Father Plumier, and found growing naturally at La Vera Cruz by Dr Houlton. It rises with a shrubby stalk, eight or ten feet high, dividing into several branches, having at their ends clusters of small scarlet-coloured flowers, succeeded by oval berries with a pulpy covering, and a hard shell with one cell, inclosing several compressed seeds. It is propagated by seeds, which should be sown soon after they are ripe; otherwise they are very apt to miscarry, or lie a year in the ground without germinating. The plants require always to be kept in a bark-love.

LORARI, among the Romans, officers whose business it was, with whips and scourges, to compel the gladiators to engage. The *lorarii* also punished slaves who disobeyed their masters.

LORD, a title of honour given to those who are noble either by birth or creation. In this sense, it amounts to much the same as *peer of the realm*, or *lord of parliament*. The title is by courtesy also given to all the sons of dukes and marquises, and to the eldest sons of earls; and it is also a title of honour bestowed on those who are honourable by their employments; as *lord advocate*, *lord chamberlain*, *lord chancellor*, &c. The word is Saxon, but abbreviated from two syllables into one; for it was originally *Illoford*,

which by dropping the aspiration became *Laford*, and afterwards by contraction *Lord*. "The etymology of the word (says J. Coates) is well worth observing; for it was composed of *ilof* "a loaf of bread," and *ford* "to give or afford;" so that *Illoford*, now *Lord*, implies "a giver of bread;" because, in those ages, such great men kept extraordinary houses, and fed all the poor; for which reason they were called *givers of bread*, a thing now much out of date, great men being fond of retaining the title, but few regarding the practice for which it was first given. See **LADY**.

House of Lords, one of the three estates of parliament, and composed of the Lords Spiritual and Temporal.

1. The *Spiritual Lords* consist of 2 archbishops and 24 bishops; and, at the dissolution of monasteries by Henry VIII, consisted likewise of 26 retired abbots and two priors: a very considerable body, and in those times equal in number to the temporal nobility. All these hold, or are supposed to hold, certain ancient baronies under the king: for William the Conqueror thought proper to change the spiritual tenure of frank-almoign or free-alms, under which the bishops held their lands during the Saxon government, into the feudal or Norman tenure by barony; which subjected their estates to all civil charges and assessments, from which they were before exempt; and in right of succession to those baronies, which were unalienable from their respective dignities, the bishops and abbots were allowed their seats in the house of lords. But though these lords spiritual are in the eye of the law a distinct estate from the lords temporal, and are so distinguished in most of our acts of parliament; yet in practice they are usually blended together under the name of *the lords*; they intermix in their votes, and the majority of such intermixture joins both estates. And from this want of a separate assembly, and separate negative of the prelates, some writers have argued very cogently, that the lords spiritual and temporal are now in reality only one estate: which is unquestionably true in every effectual sense, though the ancient distinction between them still nominally continues. For if a bill should pass their house, there is no doubt of its validity, tho' every lord spiritual should vote against it; of which Selden and Sir Edward Coke give many instances: as, on the other hand, doubtless it would be equally good, if the lords temporal present were inferior to the bishops in number, and every one of those temporal lords gave his vote to reject the bill; though this Sir Edward Coke seems to doubt of.

2. The *Temporal Lords* consist of all the peers of the realm, (the bishops not being in strictness held to be such, but merely lords of parliament,) by whatever title of nobility distinguished; dukes, marquises, earls, viscounts, or barons†. Some of these fit by descent, † See Nobility. as do all ancient peers; some by creation, as do all new-made ones; others, since the union with Scotland, by election, which is the case of the 16 peers, who represent the body of the Scots nobility. Their number is indefinite, and may be increased, at will by the power of the crown; and once, in the reign of Queen Anne, there was an instance of creating no less than 12 together; in contemplation of which, in the reign of King George I. a bill passed the house of lords, and

Lord.

was countenanced by the then ministry, for limiting the number of the peerage. This was thought by some to promise a great acquisition to the constitution, by restraining the prerogative from gaining the ascendant in that august assembly, by pouring in at pleasure an unlimited number of new-created lords. But the bill was ill relished, and miscarried in the house of commons, whose leading members were then desirous to keep the avenues to the other house as open and easy as possible.

The distinction of ranks and honours is necessary in every well-governed state: in order to reward such as are eminent for their services to the public, in a manner the most desirable to individuals, and yet without burthen to the community; exciting thereby an ambitious yet laudable ardour and generous emulation in others. And emulation, or virtuous ambition, is a spring of action which, however dangerous or invidious in a mere republic or under a despotic sway, will certainly be attended with good effects under a free monarchy; where, without destroying its existence, its excesses may be continually restrained by that superior power from which all honour is derived. Such a spirit, when nationally diffused, gives life and vigour to the community; it sets all the wheels of government in motion, which, under a wise regulator, may be directed to any beneficial purpose; and thereby every individual may be made subservient to the public good, while he principally means to promote his own particular views. A body of nobility is also more particularly necessary in our mixed and compounded constitution, in order to support the rights of both the crown and the people, by forming a barrier to withstand the encroachments of both. It creates and preserves that gradual scale of dignity which proceeds from the peasant to the prince; rising like a pyramid from a broad foundation, and diminishing to a point as it rises. It is this ascending and contracting proportion that adds stability to any government; for when the departure is sudden from one extreme to another, we may pronounce that state to be precarious. The nobility therefore are the pillars, which are reared from among the people, more immediately to support the throne; and, if that falls, they must also be buried under its ruins. Accordingly, when in the last century the commons had determined to extirpate monarchy, they also voted the house of lords to be useless and dangerous. And since titles of nobility are thus expedient in the state, it is also expedient that their owners should form an independent and separate branch of the legislature. If they were confounded with the mass of the people, and like them had only a vote in electing representatives, their privileges would soon be borne down and overwhelmed by the popular torrent, which would effectually level all distinctions. It is therefore highly necessary that the body of nobles should have a distinct assembly, distinct deliberations, and distinct powers from the commons. See also KING, NOBILITY, PARLIAMENT, COMMONS, and COMMONALTY.

As to the peculiar laws and customs relating to the house of lords: One very ancient privilege is that declared by the charter of the forest, confirmed in parliament 9 Hen. III.; viz. that every lord spiritual or temporal summoned to parliament, and passing through

the king's forests, may, both in going and returning, kill one or two of the king's deer without warrant; in view of the forester if he be present, or on blowing a horn if he be absent; that he may not seem to take the king's venison by stealth.

In the next place, they have a right to be attended, and constantly are, by the judges of the court of king's-bench and common-pleas, and such of the barons of the exchequer as are of the degree of the coif, or have been made serjeants at law; as likewise by the king's learned council, being serjeants, and by the masters of the court of chancery; for their advice in point of law, and for the greater dignity of their proceedings. The secretaries of state, with the attorney and solicitor general, were also used to attend the house of peers, and have to this day (together with the judges, &c.) their regular writs of summons issued out at the beginning of every parliament, *ad tractandum et consilium impendendum*, though not *ad consentiendum*: but, whenever of late years they have been members of the house of commons, their attendance here hath fallen into disuse.

Another privilege is, that every peer, by licence obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence: A privilege, which a member of the other house can by no means have, as he is himself but a proxy for a multitude of other people.

Each peer has also a right, by leave of the house, when a vote passes contrary to his sentiments, to enter his dissent on the journals of the house, with the reasons for such dissent; which is usually styled his protest.

All bills likewise, that may in their consequences any way affect the rights of the peerage, are by the custom of parliament to have their first rise and beginning in the house of peers, and to suffer no changes or amendments in the house of commons.

There is also one statute peculiarly relative to the house of lords; 6 Ann. c. 23. which regulates the election of the 16 representative peers of North Britain, in consequence of the 22d and 23d articles of the union: and for that purpose prescribes the oaths, &c. to be taken by the electors; directs the mode of balloting; prohibits the peers electing from being attended in an unusual manner; and expressly provides, that no other matter shall be treated of in that assembly, save only the election, on pain of incurring a præmunire. See also the articles NOBILITY and PEERS.

LORDOSIS, (of *καρδος*, bent inwards), in the medical writings, a name given to a distempered state of the spine, in which it is bent inwards, or toward the anterior parts. It is used in opposition to *gibbus*, or *hump-backed*. See SURGERY.

LORETTO, a town of Italy, in the Marca or Marche of Ancona, with a bishop's see. It is small, but fortified; and contains the famous *casa santa*, or holy chapel, so much visited by pilgrims. This chapel, according to the legend, was originally a small house in Nazareth, inhabited by the virgin Mary, in which she was saluted by the angel, and where she bred our Saviour. After their deaths, it was held in great veneration by all believers in Jesus, and at length consecrated into a chapel, and dedicated to the virgin; upon which occasion St Luke made that identical image,

Lord

||

Loretto.

Loretto.

image, which is still preserved here, and dignified with the name of our Lady of Loretto. This sanctified edifice was allowed to sojourn in Galilee as long as that district was inhabited by Christians; but when infidels got possession of the country, a band of angels, to save it from pollution, took it in their arms, and conveyed it from Nazareth to a castle in Dalmatia. This fact might have been called in question by incredulous people, had it been performed in a secret manner; but, that it might be manifest to the most short-sighted spectator, and evident to all who were not perfectly deaf as well as blind, a blaze of celestial light, and a concert of divine music, accompanied it during the whole journey; besides, when the angels, to rest themselves, let it down in a little wood near the road, all the trees of the forest bowed their heads to the ground, and continued in that respectful posture as long as the sacred chapel remained among them. But, not having been entertained with suitable respect at the castle above mentioned, the same indefatigable angels carried it over the sea, and placed it in a field belonging to a noble lady called *Lauretta*, from whom the chapel takes its name. This field happened unfortunately to be frequented at that time by highwaymen and murderers: a circumstance with which the angels undoubtedly were not acquainted when they placed it there. After they were better informed, they removed it to the top of a hill belonging to two brothers, where they imagined it would be perfectly secure from the dangers of robbery or assassination; but the two brothers, the proprietors of the ground, being equally enamoured of their new visitor, became jealous of each other, quarrelled, fought, and fell by mutual wounds. After this fatal catastrophe, the angels in waiting finally moved the holy chapel to the eminence where it now stands, and has stood these 400 years, having lost all relish for travelling.

The sacred chapel stands due east and west, at the farther end of a large church of the most durable stone of Itria, which has been built around it. This may be considered as the external covering, or as a kind of great coat to the *casa santa*, which has a smaller coat of more precious materials and workmanship nearer its body. This internal covering or case is of the choicest marble, after a plan of San Savino's, and ornamented with basso relievos, the workmanship of the best sculptors which Italy could furnish in the reign of Leo X. The subject of those basso relievos are, the history of the blessed virgin, and other parts of the Bible. The whole case is about 50 feet long, 30 in breadth, and the same in height; but the real house itself is no more than 32 feet in length, 14 in breadth, and at the sides about 18 feet in height; the centre of the roof is four or five feet higher. The walls of this little holy chapel are composed of pieces of a reddish substance, of an oblong square shape, laid one upon another, in the manner of brick. At first sight, on a superficial view, these red-coloured oblong substances appear to be nothing else than common Italian bricks; and, which is still more extraordinary, on a second and third view, with all possible attention, they still have the same appearance. Travellers, however, are assured, with great earnestness, that there is not a single particle of brick in their whole composition, being entirely of a stone, which, though it cannot now be

found in Palestine, was formerly very common, particularly in the neighbourhood of Nazareth.

Loretto.

The holy house is divided within into two unequal portions, by a kind of grate-work of silver. The division towards the west is about three-fourths of the whole; that to the east is called the *Sanctuary*. In the larger division, which may be considered as the main body of the house, the walls are left bare, to show the true original fabric of Nazareth stone; for they must not be supposed to be bricks. At the lower or western wall there is a window, the same through which the angel Gabriel entered at the Annunciation. The architraves of this window are covered with silver. There are a great number of golden and silver lamps in this chapel: one of the former, a present from the republic of Venice, is said to weigh 37 pounds, and some of the silver lamps weigh from 120 to 130 pounds. At the upper end of the largest room is an altar, but so low, that from it you may see the famous image which stands over the chimney in the small room or sanctuary. Golden and silver angels, of considerable size, kneel around her, some offering hearts of gold, enriched with diamonds, and one an infant of pure gold. The wall of the sanctuary is plated with silver, and adorned with crucifixes, precious stones, and votive gifts of various kinds. The figure of the Virgin herself by no means corresponds with the fine furniture of her house: She is a little woman, about four feet in height, with the features and complexion of a negro. Of all the sculptors that ever existed, assuredly St Luke, by whom this figure is said to have been made, is the least of a flatterer; and nothing can be a stronger proof of the blessed Virgin's contempt for external beauty, than her being satisfied with this representation of her. The figure of the infant Jesus, by St Luke, is of a piece with that of the Virgin: he holds a large golden globe in one hand, and the other is extended in the act of blessing. Both figures have crowns on their heads, enriched with diamonds: these were presents from Ann of Austria queen of France. Both arms of the Virgin are inclosed within her robes, and no part but her face is to be seen; her dress is most magnificent, but in a wretched bad taste: this is not surprising, for she has no female attendant. She has particular clothes for the different feasts held in honour of her, and, which is not quite so decent, is always dressed and undressed by the priests belonging to the chapel; her robes are ornamented with all kinds of precious stones down to the hem of her garment.

There is a small place behind the sanctuary, in which are shown the chimney, and some other furniture, which they pretend belonged to the Virgin when she lived at Nazareth; particularly a little earthen porringer, out of which the infant used to eat. The pilgrims bring rosaries, little crucifixes, and Agnus Dei's, which the obliging priest shakes for half a minute in this dish; after which it is believed they acquire the virtue of curing various diseases, and prove an excellent preventive of all temptations of Satan. The gown which the image had on when the chapel arrived from Nazareth is of red camblet, and carefully kept in a glass shrine.

Above 100 masses are daily said in this chapel, and in the church in which it stands. The jewels and riches

riches to be seen at any one time in the holy chapel are of small value in comparison of those in the treasury, which is a large room adjoining to the veltry of the great church. In the pressies of this room are kept those presents which royal, noble, and rich bigots of all ranks, have, by oppressing their subjects and injuring their families, sent to this place. To enumerate every particular would fill volumes. They consist of various utensils and other things in silver and gold; as lamps, candlesticks, goblets, crowns, and crucifixes; lambs, eagles, saints, apostles, angels, virgins, and infants: then there are cameos, pearls, gems, and precious stones, of all kinds and in great numbers. What is valued above all the other jewels is, the miraculous pearl, wherein they assert that Nature has given a faithful delineation of the Virgin sitting on a cloud with the infant Jesus in her arms. There was not room in the pressies of the treasury to hold all the silver pieces which have been presented to the Virgin. Several other pressies in the veltry are completely full. It is said that those pieces are occasionally melted down by his holiness for the use of the state; and also that the most precious of the jewels are picked out and sold for the same purpose, false stones being substituted in their room.

Pilgrimages to Loretto are not so frequent with foreigners, or with Italians of fortune and distinction, as formerly; nineteen out of twenty of those who make this journey now are poor people, who depend for their maintenance on the charity they receive on the road. To those who are of such a rank in life as precludes them from availing themselves of the charitable institutions for the maintenance of pilgrims, such journeys are attended with expence and inconvenience; and fathers and husbands, in moderate or confined circumstances, are frequently brought to disagreeable dilemmas, by the rash vows of going to Loretto which their wives or daughters are apt to make on any supposed deliverance from danger. To refuse, is considered by the whole neighbourhood as cruel, and even impious; and to grant, is often highly distressing, particularly to such husbands as, from affection or any other motive, do not choose that their wives should be long out of their sight. But the poor, who are maintained during their whole journey, and have nothing more than a bare maintenance to expect from their labour at home, to them a journey to Loretto is a party of pleasure as well as devotion, and by much the most agreeable road they can take to heaven. The greatest concourse of pilgrims is at the seasons of Easter and Whitsuntide. The rich travel in their carriages: A greater number come on horseback or on mules; or, what is still more common, on asses. Great numbers of females come in this manner, with a male friend walking by them as their guide and protector; but the greatest number of both sexes are on foot. The pilgrims on foot, as soon as they enter the suburbs, begin a hymn in honour of the Virgin, which they continue till they reach the church. The poorer sort are received into an hospital, where they have bed and board for three days.

The only trade of Loretto consists of rosaries, crucifixes, little Madonas, Agnus Dei's, and medals, which are manufactured here, and sold to pilgrims. There are great numbers of shops full of these com-

modities, some of them of a high price; but infinitely the greater part are adapted to the purses of the buyers, and sold for a mere trifle. The evident poverty of those manufacturers and traders, and of the inhabitants of this town in general, is a sufficient proof that the reputation of our Lady of Loretto is greatly on the decline.

In the great church which contains the holy chapel are confessionalis, where the penitents from every country of Europe may be confessed in their own language, priests being always in waiting for that purpose: each of them has a long white rod in his hand, with which he touches the heads of those to whom he thinks it proper to give absolution. They place themselves on their knees in groupes around the confessional chair; and when the holy father has touched their heads with the expiatory rod, they retire, freed from the burden of their sins, and with renewed courage to begin a fresh account.

In the spacious area before this church there is an elegant marble fountain, supplied with water from an adjoining hill by an aqueduct. Few even of the most inconsiderable towns of Italy are without the useful ornament of a public fountain. The embellishments of sculpture and architecture are employed with great propriety on such works, which are continually in the people's view; the air is refreshed and the eye delighted by the streams of water they pour forth; a sight peculiarly agreeable in a warm climate. In this area there is also a statue of Sixtus V. in bronze. Over the portal of the church itself is a statue of the Virgin; and above the middle gate is a Latin inscription, importing, that within is the house of the mother of God, in which the Word was made flesh. The gates of the church are likewise of bronze, embellished with basso relievos of admirable workmanship; the subjects taken partly from the Old and partly from the New Testament, and divided into different compartments. As the gates of this church are shut at noon, the pilgrims who arrive after that time can get no nearer the *santa casa* than these gates, which are by this means sometimes exposed to the first violence of that holy ardour which was designed for the chapel itself. All the sculpture upon the gates which is within reach of the mouths of those zealots, is in some degree effaced by their kisses.

There are also several paintings to be seen here, some of which are highly esteemed, particularly two in the treasury. The subject of one of these is the Virgin's Nativity, by Annibal Carracci; and of the other, a Holy Family, by Raphael. There are some others of considerable merit which ornament the altars of the great church. These altars, or little chapels, of which this fabric contains a great number, are lined with marble and embellished by sculpture; but nothing within this church interests a traveller of sensibility so much as the iron grates before those chapels, which were made of the fetters and chains of the Christian slaves, who were freed from bondage by the glorious victory of Lepanto.

The place where the governor resides stands near the church, and the ecclesiastics who are employed in it lodge in the same palace, where they receive the pilgrims of high distinction. The environs of this town are very agreeable, and in fine weather the high mountains

Lorica
||
Loricæ.

mountains of Croatia may be seen from hence. It is seated on a mountain, in E. Long. 13. 50. N. Lat. 43. 24.

LORICA, was a cuirass, brigantine, or coat of mail, in use among the Roman soldiers. It was generally made of leather, and is supposed to be derived from *lorum*.—The lorice were fet with plates of metal in various forms; sometimes in hooks or rings like a chain, sometimes like feathers, and sometimes like the scales of serpents or fishes, to which plates of gold were often added. There were other lighter cuirasses consisting only of many folds of linen cloth, or of flax made strong enough to resist weapons. Such soldiers as were rated under 1000 drachms, instead of the lorica now described, wore a *peitoralæ*.—The Roman lorica was made like a shirt, and defended the wearer both before and behind, but was so contrived that the back part could be occasionally separated from the front. Some of the lorice were made of cords of hemp or flax, close set together; whence they are called *thoracæ*, *lilicæ*, *trilicæ*, &c. from the number of the cords fixed one upon another; but these were used rather in hunting than in the field of battle.

LORICATION, or **COATING**, in chemistry, is the covering a glass or earthen vessel with a coat or crust of a matter able to resist the fire, to prevent its breaking in the performing an operation that requires great violence of fire. See **CHEMISTRY**.

LORIS, in zoology. See **LEMUR**.

LORIMERS, one of the companies of London, that make bits for bridles, spurs, and such like small iron ware. They are mentioned in statute 1 Rich. II. c. 12.—The word seems derived from the Latin word *lorum*, “a thong.”

LORME (Philibert de), one of the most celebrated architects in the 16th century, was born at Lyons. Queen Catherine de Medicis gave him the superintendence of buildings; and he had the direction of those of the Louvre, the Thuilleries, the castle of St Anet, St Germain, and other edifices erected by her orders. He wrote several books of architecture, which are esteemed; and died about the year 1577.

LORNE, a division of Argyleshire in Scotland, which gives the title of marquis to the duke of Argyle. It extends above 30 miles in length from north to south, and about nine at its utmost breadth; bounded on the east by Braidalbin; on the west, by the islands; on the north, by Lochaber; and is divided from Knapdale on the south by Loch Etive, on the banks of which stands the castle of Bergomarn, wherein the courts of justice were anciently held. This district, abounding with lakes, is the most pleasant and fertile part of Argyleshire, producing plenty of oats and barley. It once belonged to the ancient family of Macdougall, still residing on the spot; but devolved to the lords of Argyle in consequence of a marriage with the heiress, at that time a branch of the Stuart family. The chief place of note in this district is the castle of Dunstaffnage, a seat of the Scottish kings previous to the conquest of the Picts in 843 by Kenneth II. In this place was long preserved the famous stone, the palladium of North Britain; brought, says legend, out of Spain, where it was first used as a seat of justice by Gathelus, coeval with Moses. It continued here as the coronation-chair till the reign of

Lorrie,
Lorrain.

Kenneth II. who removed it to Scoone, in order to secure his reign; for, according to the inscription,

*Ni sollet situm, Scoti quocunque locatum
Invocient lapidem, regnare te auctor ibidem.*

Some of the ancient regalia were preserved till the present century, when the keeper's servants, during his infirm years, embellished them for the silver ornaments; and left only a battle-axe, nine feet long, of beautiful workmanship, and ornamented with silver.

The castle is square; the inside only 87 feet; partly ruinous, partly habitable. At three of the corners are round towers; one of them projects very little. The entrance is towards the sea at present by a staircase, in old times probably by a draw-bridge, which fell from a little gate-way. The masonry appears very ancient; the tops battlemented. This pile is seated on a rock at the mouth of Loch Etive, whose waters expand within to a beautiful bay, where ships may safely ride in all weather. Of this building, the founder of which is unknown, nothing remains except the outer walls, which, though roofless, are still in good order; and within which some buildings have been erected, which serve as the residence of the laird. The duke of Argyle is hereditary keeper under the Crown.—At a small distance from the castle is a ruined chapel, once an elegant building; and at one end an inclosure, a family-cemetery. Opposite to these is a high precipice, ending abrupt and turning suddenly toward the south-east. A person concealed in the recesses of the rock, a little beyond the angle, surprises friends stationed at some distance beneath the precipice with a very remarkable echo of any word, or even sentence, he pronounces; which reaches the last distinct and unbroken. The repetition is single, but remarkably clear.

In 1397, this castle was possessed by Alexander Macdougall lord of Argyle, a friend to the English; but was that year reduced by Robert Bruce, when Macdougall sued for peace with that prince, and was received into favour.

We find, about the year 1455, this to have been a residence of the lords of the isles; for here James last earl of Douglas, after his defeat in Annandale, fled to Donald, the regulus of the time, and prevailed on him to take arms and carry on a plundering war against his monarch James II.

The situation of this regal seat was calculated for pleasure as well as strength. The views of mountains, valleys, waters, and islands, are delightful. On the north side of Loch Etive stood the town of Beregonium, supposed to have been the capital of the West Highlands. It seems, from certain mounds, excavations, and other appearances, to have been a strong fortress, to prevent invasion, or to secure a retreat, as occasions might require. On the bank of the same loch is the site of Ardhattan, a priory of monks of Valliscaulium in Burgundy, founded in 1230 by Donald Macdougall, ancestor of the Macdougalls of Lorne. Here Robert Bruce, who remained master of this country before he got entire possession of Scotland, held a parliament or council.—The country abounds in Druidical, Danish, and other monuments.

LORRAIN, a sovereign state of Europe, bounded on the north by Luxemburg and the archbishopric of Treves, on the east by Alsace and the duchy of Deux

Ponts,

Lorraine,
Loten.

Ponts, on the south by Franche Comté, and on the west by Champagne and the duchy of Bar. It is about 100 miles in length, and 75 in breadth; and abounds in all sorts of corn, wine, hemp, flax, rape-seed, game, and fish, with which it carries on some trade, and in general all the necessaries of life. There are fine meadows and large forests, with mines of iron, silver, and copper, as also salt-pits. There are a great number of rivers; of which the principal are the Maas or Meuse, the Moselle, the Scille, the Meure, and the Sarre. It is divided into three parts; the duchy of Lorraine, properly so called, which was heretofore a sovereign state; the duchy of Barr, which formerly belonged to the dukes of Lorraine, but afterwards came under the government of France; and the third comprehends the three bishoprics of Metz, Toul, and Verdun, which have belonged to France ever since the year 1552. In 1733, the emperor of Germany being at war with France, this last got possession of the duchy of Lorraine; and when there was a peace made in 1735, it was agreed, that Stanislaus king of Poland, father-in-law to the king of France, should possess these duchies, and that after his death they should be united for ever to the crown of France. It was also then agreed, that Francis Stephen, duke of Lorraine, and the emperor's son-in-law, should have the grand duchy of Tuscany as an equivalent for Lorraine. After the death of the great duke of Tuscany, in 1737, King Stanislaus and the duke of Lorraine took possession of their respective dominions, and the cessation was confirmed and guaranteed by a treaty in 1738. The inhabitants are laborious and valiant, and their religion is the Roman Catholic. They have but little trade with strangers, because they have no navigable rivers, and because they have all necessaries within themselves; but what little trade they have consists of corn and linen cloth. Nancy is the capital town.

LORRAIN (Robert le), an eminent sculptor, born at Paris in 1666. From his infancy, he made so rapid a progress in the art of designing, that at the age of 18 the celebrated Girardon intrusted him with the care of teaching his children and correcting his disciples. He committed to him also, in conjunction with Noulisson, the execution of the famous tomb of Cardinal Richelieu in the Sorbonne, and his own tomb at St Landres in Paris. On his return from Rome, he finished several pieces at Marfeilles, which had been left imperfect by the death of Mr Puget. He was received into the academy of sculpture in 1701. His *chief d'œuvre* is Galatea, a work universally admired. Lorraine afterwards made a Bacchus for the gardens at Versailles, a Faun for those of Marly; and several bronzes, among which is an Andromeda; all in an excellent taste. This artist succeeded chiefly in heads; and more particularly in that of young girls, which he performed with incomparable delicacy and truth.

LORRAIN (Claude.) See CLAUDE.

LOTEN (John), a good landscape painter of the English school; though a native of Switzerland. His taste led him to solemn and dreary scenes, as landstorms accompanied with showers of rain, &c. and he seldom omitted to introduce oak-trees in his prospects; his landscapes are generally large; and he painted with nature, truth, and force. But the effect of his composition had been much greater if he had been less cold

Nº 188.

in his colouring: for the judicious eye is not pleased with the darkish tint that predominates in it. He died in London about 1681.

Lothian.

LOTHIAN, a name given to three counties of Scotland, viz. Haddington-shire, Edinburgh-shire, and Linlithgow-shire; otherwise called *East, Mid, and West Lothians*.

1. East Lothian, or Haddington-shire, is bounded on the north-west by the Frith of Forth; and on the east by the German Sea; on the south-east by Berwickshire; and on the west by the county of Edinburgh. It extends about 25 miles from east to west, and where broadest, nearly 15 from north to south. The coast, advancing northward into the Frith, forms an irregular curve.—This is one of the most fruitful counties in Scotland, producing great quantities of wheat and all sorts of grain, well-watered, and plentifully supplied with fish, fowl, fuel, and all the necessaries of life. It abounds with towns, villages, and farms, interperfed with a great number of agreeable houses belonging to persons of rank and fortune. For cultivation, populousness, and fertility, this shire may vie with any tract of land in the island of Great Britain. Over and above the farming, which turns out to great account, the people towards the sea-coast employ themselves in the fishery, salt-making, and in foreign trade; and some of the more inland inhabitants engage in the linen and woollen manufactures. Limestone and coal are found in most parts of the country, and great numbers of sheep are fed on the hills of Lammermuir.

2. Edinburgh-shire, or Mid-Lothian, is about 35 miles long, but varies in its breadth in different places from five to 16 miles. It is bounded on the east by Haddington-shire; on the west by the shire of Linlithgow; on the south, by Tweeddale or Peebles-shire; and on the north, by part of West-Lothian and the Frith of Forth. The aspect of the country is in general level and pleasant, interperfed with a few hills, that help to exhibit agreeable prospects. It is well watered with rivers, and shaded with woods. It produces plenty of coal, lime-stone, a soft black marble, and some copper ore. The soil, of itself fertile, is finely cultivated, and yields as plentiful harvests of excellent wheat as are found in any part of Great Britain. The whole shire is interperfed with noble houses and plantations belonging to noblemen and gentlemen of fortune. The farmers are master of the science of agriculture; and wealthy in consequence of their skill, some of them paying 500*l.* of yearly rent. The country is well inhabited, and presents us with a good number of towns and populous villages. Along the sea-coast the common people subsist by fishing, and traffic in coals and salt, and some few carry on a smuggling commerce. Those in the inland are employed in farming, and some branches of the weaving manufacture. The sheriffalty of this shire is in the gift of the crown; and Edinburgh is a county in itself.

3. The shire of Linlithgow, or West Lothian, is bounded on the north by the Frith of Forth. The small river Almond divides it from Edinburgh-shire on the east. On the south-west it joins the county of Lanerk; and on the west it is parted from Stirling-shire by Avon, a small river. Its form, though irregular,

Lotion
||
Lottery.

regular, approaches to a parallelogram. It measures from north-east to south-west, nearly 20 miles. Its breadth, except on the shore of the Frith, does not exceed 12.—The country is pleasant and fertile, abounding with corn and pasturage. Here is found plenty of coal, limestone, and lead ore; nay, in the reign of James VI. it produced a rich mine of silver.

LOTION, is, strictly speaking, such washing as concerns beautifying the skin, by cleansing it of those deformities which a distempered blood throws upon it. Medicines of this kind, however, are for the most part insignificant, and sometimes very dangerous; the only proper method of treating these disorders is, by administering such medicines as tend to correct the morbid state of the constitution from whence they arise.

LOTION, in pharmacy, denotes a preparation of medicines, by washing them in some liquid, either made very light, so as to take away only the dregs; or sharp, so as to penetrate them, in order to clear them of some salt, or corrosive spirit as is done to antimony, precipitates, magisteries, &c. or intended to take away some foulness or ill quality, or to communicate some good one.

LOTAPHAGI (anc. geog.), a people of the Regio Syrtica (so called from their living on the lotus); inhabiting between the two Syrtis, from the Cynusphus to the Triton. The lotus was said to be a food so luscious, as to make strangers forget their native country. A sweet wine was expressed from it, which did not keep above ten days, (Pliny). Lotophagi of Homer. See MENINX.

LOTTERY, a kind of public game at hazard, frequent in Britain, France, and Holland, in order to raise money for the service of the state; being appointed with us by the authority of parliament, and managed by commissioners appointed by the lords of the treasury for that purpose. It consists of several numbers of blanks and prizes, which are drawn out of wheels, one of which contains the numbers, and the other the corresponding blanks or prizes.

The Romans invented lotteries to enliven their Saturnalia. This festival began by the distribution of tickets which gained some prize. Augustus made lotteries which consisted of things of little value; but Nero established some for the people, in which 1000 tickets were distributed daily, and several of those who were favoured by Fortune got rich by them. Heliogabalus invented some very singular: the prizes were either of great value or of none at all; one gained a prize of six slaves, and another of six flies; some got valuable vases, and others vases of common earth. A lottery of this kind exhibited an excellent picture of the inequality with which Fortune distributes her favours.

The first English lottery we find mentioned in history was drawn A. D. 1569. It consisted of 40,000 lots, at 10s. each lot: the prizes were plate; and the profits were to go towards repairing the havens of this kingdom. It was drawn at the west door of St Paul's cathedral. The drawing began on the 11th of January 1569, and continued incessantly drawing, *day and night*, till the 6th of May following; as Maitland, from Stowe, informs us in his History, Vol. I. p. 217. There were then only three lottery-offices in London. The proposals for this lottery were published

Vol. X. Part I.

in the years 1567 and 1568. It was at first intended to have been drawn at the house of Mr Dericke, her majesty's servant (*i. e.* her jeweller), but was afterwards drawn as above mentioned.

Dr Rawlinson showed the Antiquary Society, 1748, "A proposal for a very rich lottery, general without any blanks, containing a great number of good prizes, as well of ready money as of plate and certain sorts of merchandizes, having been valued and prized by the commandment of the queen's most excellent majesty's order, to the extent that such commodities as may chance to arise thereof after the charges borne may be converted towards the reparations of the havens and strength of the realm, and towards such other public good works. The number of lots shall be four hundred thousand, and no more; and every lot shall be the sum of tenne shillings sterling, and no more. To be filled by the seal of St Bartholomew. The shew of prizes are to be seen in Cheapside, at the sign of the Queen's Armes, the house of Mr Dericke, goldsmith, servant to the queen. Some other orders about it in 1567-8. Printed by Hen. Bynneyman."

"In the year 1612, king James, in special favour for the present plantation of English colonies in Virginia, granted a lottery, to be held at the west end of St Paul's; whereof one Thomas Sharplys, a taylor of London, had the chief prize, which was 4000 crowns in fair plate," Baker's Chronicle.

In the reign of queen Anne, it was thought necessary to suppress lotteries, as nuisances to the public. Since that time, however, they have been licensed by an act of parliament, under various regulations. The act passed in 1778 restrains any person from keeping an office for the sale of tickets, shares, or chances, or for buying, selling, insuring, or registering, without a licence; for which licence each office-keeper must pay 50l. to continue in force for one year, and the produce to be applied towards defraying the expences of the lottery. And no person is allowed to sell any share or chance less than a sixteenth, on the penalty of 50l. All tickets divided into shares or chances are to be deposited in an office, to be established in London by the commissioners of the treasury, who are to appoint a person to conduct the business thereof; and all shares are to be stamped by the said officer, who is to give a receipt for every ticket deposited with him. The numbers of all tickets so deposited are to be entered in a book, with the names of the owners, and the number of shares into which they are divided; and twopence for each share is to be paid to the officer on depositing such tickets, who is therewith to pay all expences incident to the office. All tickets deposited in the office are to remain there three days after the drawing. And any person keeping an office, or selling shares, or who shall publish any scheme for receiving moneys in consideration of any interest to be granted in any ticket in the said lottery, &c. without being in possession of such ticket, shall forfeit 500l. and suffer three months imprisonment. And no business is to be transacted at any of the offices after eight in the evening, except on the evening of the Saturday preceding the drawing. No person is to keep any office for the sale of tickets, &c. in Oxford or Cambridge, on penalty of 20l. Before this regulating statute took place, there were upwards of 400 lottery offices in

Lotus.

and about London only; but the whole number afterwards, for all Britain, as appeared by the list published by authority, amounted to no more than 51.

LOTUS, or BIRD'S-FOOT TREFOIL, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionacea*. The legumen is cylindrical, and very erect; the alæ closing upwards longitudinally; the calyx is tubulated. There are many species, but only five or six are usually cultivated in our gardens. 1. The tetragonolobus, or winged pea, hath trailing, slender, branchy stalks, about a foot long, garnished with trifoliate oval leaves; and, from the axillas of the branches, large, papilionaceous red flowers, one on each footstalk; succeeded by tetragonous solitary pods, having a membranous wing or lobe, running longitudinally at each corner. It flowers in June and July, and the seeds ripen in autumn. 2. The creticus, or Cretan silvery lotus, hath a slender under shrubby stalk, rising by support three or four feet high, ornamented with trifoliate, bright, silvery leaves; and branches terminated by several yellow flowers succeeded by subternate pods. 3. The Jacobæus, or lotus of St James's island, hath upright herbaceous stalks branching two or three feet high, and, from the upper part of the branches, long slender footstalks, terminated each by three or five yellowish purple flowers, appearing most part of the summer and autumn, and succeeded by subternate pods filled with plenty of seeds. 4. The hirsutus, or hairy Italian lotus, hath upright hairy stalks branching a yard high; and terminated by heads of whitish hoary-cupped flowers appearing in June, which are succeeded by oval pods full of seed, which ripens in autumn. 5. The dorycnium, white Austrian lotus, or shrub-trefoil of Montpellier, has under shrubby smooth stalks, branching three or four feet high, and the branches terminated by aphyllous heads of small white flowers appearing in June, succeeded by short pods. 6. The edulis, sends forth several trailing stalks about a foot long, furnished at their joints with trifoliate, roundish, smooth leaves, having oval stipule. The flowers come singly from the sides of the stalks, on long peduncles, with three oval floral leaves, the length of the flower: the latter is small, yellow; and is succeeded, by a thick arched pod, having a deep furrow on its outside.

Cultures, &c. The first species is a hardy annual, and is easily raised from seed sown any time from the month of February to May; the plants requiring no other culture than to be kept free from weeds. It was formerly cultivated as an esculent; for its young green feed-pods may be dressed and eat like peas, or in the manner of kidney-beans. The other species may be propagated either by seeds or cuttings, but require to be kept in pots in the green-house during the winter-season. — The sixth species is an annual, and a native of several parts of Italy, where the inhabitants eat the young pods as we do kidney beans. The green pods of the first species were formerly gathered in this country, and dressed in the manner of kidney beans, and are used

to still in some of the northern counties of England; but they are coarse, and not very agreeable to such as have been accustomed to feed upon better fare.

Lotus of Homer. See DIOSPYROS.

Libyan Lotus. See RHAMNUS.

LOVAGE, in botany. See LIGUSTICUM.

LOVE, in a large sense of the word, denotes all those affections of the pleasing kind which objects and incidents raise in us: thus we are said to *love* not only intelligent agents of morally good dispositions, but also sensual pleasures, riches, and honours. But

Love, in its usual and more appropriate signification, may be defined, "that affection which, being compounded of animal desire, esteem, and benevolence, becomes the bond of attachment and union between individuals of the different sexes; and makes them feel in the society of each other a species of happiness which they experience no where else." We call it an *affection* rather than a *passion*, because it involves a desire of the happiness of its object: And that its constituent parts are those which have been just enumerated, we shall first endeavour to prove, and then proceed to trace its rise and progress from a selfish appetite to a generous sentiment

Animal desire is the actual energy of the sensual appetite: and that it is an essential part of the complex affection, which is properly called *love*, is apparent from this consideration, that though a man may have sentiments of esteem and benevolence towards women who are both old and ugly, he never supposes himself to be in love of any woman, to whom he feels not the sensual appetite to have a stronger tendency than to other individuals of her sex. On the other hand, that animal desire *alone* cannot be called the affection of love is evident; because he who gratifies such a desire without esteeming its object, and wishing to communicate at the same time that he receives enjoyment, loves not the woman, but himself. Mere animal desire has nothing in view but the species and the sex of its object; and before it make a selection, it must be combined with sentiments very different from itself. The first sentiment with which it is combined, and by which a man is induced to prefer one woman to another, seems to be that by which we are delighted with gracefulness of person, regularity of features, and beauty of complexion. It is not indeed to be denied that there is something irresistible in female beauty. The most severe will not pretend, that they do not feel an immediate prepossession in favour of a handsome woman; but this prepossession, even when combined with animal desire, does not constitute the whole of that affection which is called *love*. Savages feel the influence of the sensual appetite, and it is extremely probable that they have some ideas of beauty; but among savages the affection of love is seldom felt. Even among the lower orders in civil society it seems to be a very gross passion, and to have in it more of the selfishness of appetite than of the generosity of esteem. To these observations many exceptions will no doubt be found (A): but

Love.

(A) Such as the negroes whose story is so pathetically told by Addison in N^o 215 of the *Spectator*; the two lovers who were killed by lightning at Staunton Harcourt, August 9th 1718, (*see Pope's Letters*); and many others which will occur to every reader.

Love. but we speak of savages in general, and of the great body of the labouring poor, who in the choice of their mates do not study—who indeed are incapable of studying, that rectitude of mind and those delicacies of sentiment, without which neither man nor woman can deserve to be esteemed.

In the savage state, and even in the first stages of refinement, the bond of union between the sexes seems to consist of nothing more than mere animal desire and instinctive tenderness for their infant progeny. The former impels them to unite for the propagation of the species; and the latter preserves the union till the children, who are the fruit of it, be able to provide for their own subsistence. That in such unions, whether casual or permanent, there is no mutual esteem and benevolence, is apparent from the state of subjection in which women are held in rude and uncultivated nations, as well as from the manner in which marriages are in such nations contracted.

Sweetness of temper, a capital article with us in the female character, displays itself externally in mild looks and gentle manners, and is the first and perhaps the most powerful inducement to love in a cultivated mind. "But such graces (says an ingenious writer*) are scarce discernible in a female savage; and even in the most polished woman would not be perceived by a male savage. Among savages, strength and boldness are the only valuable qualities. In these, females are miserably deficient; for which reason they are contemned by the males as beings of an inferior order. The North American tribes glory in idleness: the drudgery of labour degrades a man in their opinion, and is proper for women only. To join young persons in marriage is accordingly the business of the parents; and it would be unpardonable meanness in the bridegroom to show any fondness for the bride. In Guiana a woman never eats with her husband, but after every meal attends him with water for washing; and in the Caribbee islands she is not permitted to eat even in the presence of her husband. Dampier observes in general, that among all the wild nations with which he was acquainted, the women carry the burdens, while the men walk before and carry nothing but their arms; and that women even of the highest rank are not better treated. In Siberia, and even in Russia, the capital excepted, men till very lately treated their wives in every respect like slaves. It might indeed be thought, that animal desire, were there nothing else, should have raised women to some degree of estimation among men; but male savages, utter strangers to decency and refinement, gratify animal desire with as little ceremony as they do hunger or thirst.

"Hence it was that in the early ages of society a man purchased a woman to be his wife as one purchases an ox or a sheep to be food; and valued her only as

she contributed to his sensual gratification. Instances innumerable might be collected from every nation of which we are acquainted with the early history; but we shall content ourselves with mentioning a few. Abraham bought Rebekah and gave her to his son Isaac for a wife†. Jacob having nothing else to give, served † Gen. xxi. Laban 14 years for two wives†. To David, demanding Saul's daughter in marriage, it was said, "The king desireth not any dowry, but an hundred foreskins of the Philistines†." In the Iliad Agamemnon offers † 1 Sam. his daughter to Achilles for a wife, and says that he xviii. 28. would not demand for her any price §. By the laws § Lib. ix. of Ethelbert king of England, a man who committed adultery with his neighbour's wife was obliged to pay the husband a fine, and to buy him another wife. || But it is needless to multiply instances; the practice has prevailed universally among nations emerging from the savage state, or in the rudest stage of society: and wherever it prevailed, men could not possibly have for the fair sex any of that tender regard and esteem which constitute so essential a part of the complex affection of love.

Accordingly we find the magnanimous Achilles an absolute stranger to that generous affection, though his heart was susceptible of the warmest and purest friendship. His attachment to Patroclus was so heroically disinterested, that he willingly sacrificed his own life to revenge the death of his friend; but when Agamemnon threatened to rob him of his favourite female captive, though he felt the insult offered to his pride, he never spoke of the woman but as a slave whom he was concerned to preserve in point of honour, and as a testimony of his glory. Hence it is that we never hear him mention her but as his spoil, the reward of war, or the gift which the Grecians gave him.

"And dar'st thou threat to snatch my prize away,
"Due to the deeds of many a dreadful day?
"A prize as small, O tyrant! match'd with thine,
"As thy own actions if compar'd with mine.
"Thine in each conquest is the wealthy prey,
"Tho' mine the sweat and danger of the day.
"Some trivial present to my ships I bear,
"Or barren praises pay the wounds of war."

And again, after upbraiding the general with his tyranny and want of regard to merit, he adds, with the greatest indifference as to the charms of the woman,

"Seize on Briseis, whom the Grecians doom'd
"My prize of war, yet tamely give up!
"And seize secure, no more Achilles draws
"His conquering sword in any woman's cause.
"The gods command me to forgive the pain;
"But let this first invasion be the last:
"For know, thy blood, when next thou dar'st invade,
"Shall stream in vengeance on my reeking blade."

Pope has made the language of this rough warrior less inconsistent with the peculiar resentment natural to an injured lover than it is in the original (a); but from the

P p z the

(a) The original passages are :

Και δὴ μοι γέρας αἶψας ἀπαρτίσθαι στείλεις,
Εἴ μοι πόλιν ἔμελλεν, δόλον δὲ μοι νῆς Ἀχαιοῖν.
Οὐ μὲν τοὶ πόλιν ἔγω γέρας, σπέντο Ἀχαιοὶ
Τρώων ὑπερσφον ὑπερσφον ὑπὸ πλοῦτον.
Ἀλλὰ το μὲν πλοῦτον πολέμοιοις πόλιν οἶον
Στείλει μοι δῖος ἄταρ νηὶ πόλιν δαίμονος ἐκείνου,
Σοὶ το γέρας ποῦ μείζον, ἔγω δ' ὄλγιστον τί φίλον τέ
Ἐρχομαι ἔγω ἐπὶ νῆας ὑπὸ πλοῦτον πολέμοιοις.

Iliad, Lib. I.

And, Ἀλλὰ δὲ τοι γέρας, σὺ δ' ἐνὶ φρεσὶ βάλλεις σπέν
Χίρην μοι νῆαυτι γέρας μακροτέρην, ἵππικα κούρην,
Οὐτε σοι, σὺ γὰρ ἄλλω, ἐγὼ δὲ φησὶν ἐπὶ δόλῳ.
Τὸν δ' Ἀχαιοί, ἃ μοι ἐστὶ νῆαυτι πλοῦτον ἰσχυρὴν,
Τὸν οὐκ αὖ το γέρας αἶψας ἀπαρτίσθαι στείλει.
Εἰ δ' ἄρτι μοι, χίρην, ἡν ὑπομένω μοι πόλιν
Ἄψα το αἶψα χίρην ἰσχυρὴν ὑπὸ πλοῦτον.

In this latter passage the hero says expressly, "I will not fight with you or with any other man for the sake of a girl; you shall not rob me of any other part of my property;" which is surely the language of a man to whose heart love must have been an utter stranger.

Love.

Lib. ix.

Sec. 31.

* Sketches of
the History
of Man.

the last quoted passage, even as translated by him, it is apparent that Achilles would have been equally hurt had Agamemnon threatened to deprive him of any other part of his plunder. Accordingly he yields up Briseis, not in grief for a mistress whom he loses, but in fullness for an injury that is done him. Nor let it be imagined, that this coldness proceeded from the pride of the hero, which would not permit him to acknowledge his love of a captive. With the generous affection of love captives and princesses were equally incapable of inspiring him. He repeatedly affirmed indeed that he delighted in his fair Lyrnessian slave, but it was only as an instrument of sensual gratification; for as to every thing else in a woman, he was so totally indifferent, that he declared he would not, when he should be disposed to marry, give himself the trouble to make a choice, but leave the whole matter to his father.

"If heav'n restore me to my realms with life,

"The rev'rend Pelus shall elect my wife."

Even Agamemnon, of whom Pope and Madam Dacier think more favourably as a lover, speaks the very same language when mentioning his favourite captive Chryseis. In his furious debate with Achilles he calls her indeed

"A maid, unmatch'd in manners as in face,

"Skill'd in each art, and crown'd with ev'ry grace."

And adds,

"Not half so dear were Glytemnestra's charms,

"When first her blooming beauties blest my arms."

But this was said merely to enhance the value of the prize, which for the public good he was about to resign; for that she was dear to him only as ministering to his pleasure, is past dispute from the language which he had previously held with her father, as well as from his requiring grateful Greece to pay a just equivalent, and to repair his *private loss*. A man who really loved would have thought nothing an equivalent for the object of his love; much less would he have insinuated to her father a possibility of his dismissing from his embrace a woman whom he esteemed, when time should have robbed her of every youthful grace.

Since, then, it is so apparent, that in the heroic age of Greece even princes and kings were strangers to the generous affection of love, it needs not occasion much surprise that the same affection has very little influence upon mankind in the lowest ranks of the most polished societies of modern Europe. That this is actually the case, that among the generality of uneducated men and women there is no other bond of attachment than the sensual appetite, every year furnishes multiplied proofs. We daily see youths, rejected by their mistresses, paying their addresses without delay to girls who, in looks, temper, and disposition, are diametrically opposite to those whom so lately they pretended to love: We daily see maidens, slighted by their lovers, receiving the addresses of men, who, in nothing but their sex, resemble those to whom a week before they wished to be married: and we believe it is not very uncommon to find a girl entertaining several lovers together, that if one or more of them should prove false, she may still have a chance not to be totally deserted. Did esteem and benevolence, placed on manners and character, constitute any part of vulgar love, these people would act very differently; for they would

find it impossible to change their lovers and their mistresses with the same ease that they change their cloaths.

To this account of love, as it appears in savage nations, some one may perhaps oppose the paintings of the softer passion in the poems of Ossian. That bard describes the female character as commanding respect and esteem, and the Caledonian heroes as cherishing for their mistresses a flame so pure and elevated as never was surpassed, and has seldom been equalled, in those ages which we commonly call most enlightened. This is indeed true: and it is one of the many reasons which have induced Johnson and others to pronounce the whole a modern fiction. Into that debate we do not enter. We may admit the authenticity of the poems, without acknowledging that they furnish any exception to our general theory. They furnish indeed in the manners which they describe a wonderful anomaly in the general history of man. All other nations of which we read were in the hunter-state savage and cruel. The Caledonians, as exhibited by Ossian, are gentle and magnanimous. The heroes of Homer fought for plunder, and felt no clemency for a vanquished foe. The heroes of Ossian fought for fame; and when their enemies were subdued, they took them to their bosoms. The first of Greeks committed a mean insult on the dead body of the first of Trojans. Among the Caledonians insults offered to the dead, as well as cruelty to the living, were condemned as infamous. The heroes of Ossian appear in no instance as savages. How they came to be polished and refined before they were acquainted with agriculture and the most useful arts of life, it is not our business to enquire; but since they unquestionably were so, their treatment of the female sex, instead of opposing, confirms our theory; for we never conceived rich cloaths, superb houses, highly-dressed food, or even the knowledge of foreign tongues, to be necessary to the acquisition of a generous sentiment. Luxury indeed appears to be as inimical to love as barbarism: and we believe, that in modern nations the tender and exalted affection which deserves that name is as little known among the highest orders of life as among the lowest. Perhaps the Caledonian ladies of Ossian resembled in their manners the German ladies of Tacitus, who accompanied their husbands to the chase, fought by their sides in battle, and partook with them of every danger. If so, they could not fail to be respected by a race of heroes among whom courage took place of all other virtues: and this single circumstance, from whatever cause it might proceed, will sufficiently account for the estimation of the female character among the ancient Germans and Caledonians, so different from that in which it has been held in almost every other barbarous nation.

But if among savages and the vulgar, love be unknown, it cannot possibly be an instinctive affection: and therefore it may be asked, How it gets possession of the human heart; and by what means we can judge whether in any particular instance it be real or imaginary? These questions are of importance, and deserve to be fully answered; though many circumstances conspire to render it no easy task to give to them such answers as shall be perfectly satisfactory. Love can subsist only between individuals of the different sexes. A man can hardly love two women at the same time; and

Love.

and we believe that a woman is still *left* capable of *loving at once more than one man*. Love, therefore, has a natural tendency to make men and women pair, or, in other words, it is the source of marriage: but in polished society, where alone this affection has any place, so many things besides mutual attachment are necessary to make the married life comfortable, that we rarely see young persons uniting from the impulse of love, and have therefore but few opportunities of tracing the rise, progress, and consequences of the affection. We shall, however, throw together such reflections as have occurred to us on the subject, not without indulging a hope, that they may be useful to the younger part of our readers when forming the most important connection in life.

We have said, that the perception of beauty, combined with animal desire, is the first inducement which a man can have to prefer one woman to another. It may be added, that elegance of figure, a placid masculine countenance, with a person which indicates strength and agility, are the qualities which first tend to attach any woman to a particular man. Beauty has been defined †, “That particular form, which is the most common of all particular forms to be met with in the same species of beings.” Let us apply this definition to our own species, and try, by means of it, to ascertain what constitutes the beauty of the human face. It is evident, that of countenances we find a number almost infinite of different forms, of which forms one only constitutes beauty, whilst the rest, however numerous, constitute what is *not* beauty, but *deformity*, or *ugliness*. To an attentive observer, however, it is evident, that of the numerous particular forms of *ugliness*, there is not one which includes so many faces as are formed after that particular cast which constitutes *beauty*. Every particular species of the animal as well as of the vegetable creation, may be said to have a fixed or determinate form, to which, as to a centre, nature is continually inclining. Or it may be compared to pendulums vibrating in different directions over one central point; and as they *all* cross the centre, though only one passes through any *other point*; so it will be found that *perfect beauty* is oftener produced by nature than deformity: we do not mean then deformity in *general*, but than any *one kind and degree* of deformity. To infringe in a particular part of a human feature: the line which forms the ridge of the nose is deemed beautiful when it is *straight*; but this is likewise the *central form*, which is oftener found than any *one particular degree* of *concave*, *convex*, or any *other* irregular form that shall be proposed. As we are then more accustomed to beauty than deformity, we may conclude that to be the reason why we approve and admire it, just as we approve and admire fashions of dress for no other reason than that we are used to them. The same thing may be said of colour as of form; it is custom alone which determines our preference of the colour of the *Europeans* to that of the *Ethiopians*, and which makes them prefer their own colour to ours; so that though habit and custom cannot be the cause of beauty (see *BEAUTY*), they are certainly the cause of our liking it.

That we *do like* it cannot be denied. Every one is conscious of a pleasing emotion when contemplating beauty either in man or woman; and when that plea-

sure is combined with the gratification of the sensual appetite, it is obvious that the sum of enjoyment must be greatly increased. The perception of beauty, therefore, necessarily directs the energy of the sensual appetite to a *particular* object; but still this combination is a mere selfish feeling, which regards its object only as the *best* of many similar instruments of pleasure. Before it can deserve the name of *love*, it must be combined with esteem, which is never belittled but upon moral character and internal worth; for let a woman be ever so beautiful, and of course ever so desirable as an instrument of sensual gratification, if she be not possessed of the virtues and dispositions which are peculiar to her sex, she will inspire no man with a generous affection. With regard to the outlines, indeed, whether of internal disposition or of external form, men and women are the same; but nature, intending them for mates, has given them dispositions, which, though concordant, are, however, different, so as to produce together delicious harmony. “The man, more robust, is fitted for severe labour, and for field exercises; the woman, more delicate, is fitted for sedentary occupations, and particularly for nursing children. The man, bold and vigorous, is qualified for being a protector ‡; the woman, delicate and timid, † *Seesteele* of *Min.* requires protection. Hence it is, that a man never admires a woman for possessing bodily strength or personal courage; and women always despise men who are totally destitute of these qualities. The man, as a protector, is directed by nature to govern; the woman, conscious of inferiority, is disposed to obey. Their intellectual powers correspond to the destination of nature. Men have penetration and solid judgment to fit them for governing; women have sufficient understanding to make a decent figure under good government: a greater proportion would excite dangerous rivalry between the sexes, which nature has avoided by giving them different talents. Women have more imagination and sensibility than men, which make all their enjoyments more exquisite; at the same time that they are better qualified to communicate enjoyment. Add another capital difference of disposition: the gentle and insinuating manners of the female sex tend to soften the roughness of the other sex; and wherever women are indulged with any freedom, they polish sooner than men.

“There are not the only particulars that distinguish the sexes. With respect to the ultimate end of love, it is the privilege of the male, as superior and protector, to make a choice: the female, preferred, has no privilege but barely to consent or to refuse. Whether this distinction be the immediate result of the originally different dispositions of the sexes, or only the effect of associations inevitably formed, may be questioned; but among all nations it is the practice for men to court, and for women to be courted: and were the most beautiful woman on earth to invert this practice, she would forfeit the esteem, however by her external grace she might excite the desire, of the man whom she addressed. The great moral virtues which may be comprehended under the general term *integrity*, are all absolutely necessary to make either men or women estimable; but to procure esteem to the female character, the modesty peculiar to their sex is a very essential circumstance. Nature hath provided them with it as a defence against the artful solicitations of the other sex.

Love.

† By Peter Buffier in his *First Truths*, and Sir Joshua Reynolds in the *Adler*.

‡ See *Seesteele* of *Min.*

sex before marriage, and also as a support of conjugal fidelity."

A woman, therefore, whose dispositions are gentle, delicate, and rather timid than bold, who is possessed of a large share of sensibility and modesty, and whose manners are soft and insinuating, mult, upon moral principles (see MORAL PHILOSOPHY), command the esteem and benevolence of every individual of the other sex who is possessed of sound understanding; but if her person be deformed, or not such as to excite some degree of animal desire, she will attract no man's love. In like manner, a man whose moral character is good, whose understanding is acute, and whose conversation is instructive, mult command the esteem of every sensible and virtuous woman; but if his figure be disagreeable, his manners unpolished, his habits slovenly, and above all, if he be deficient in personal courage, he will hardly excite desire in the female breast. It is only when the qualities which command esteem are, in the same person, united with those which excite desire, that the individual so accomplished can be an object of love to one of the other sex; but when these qualities are thus united, each of them increases the other in the imagination of the lover. The beauty of his mistress gives her, in his apprehension, a greater share of gentleness, modesty, and every thing which adorns the female character, than perhaps the really possesses; whilst his persuasion of her internal worth makes him, on the other hand, apprehend her beauty to be absolutely unrivalled.

To this theory an objection readily offers itself, which it is incumbent upon us to obviate. Men and women sometimes fall in love at first sight, and very often before they have opportunities of forming a just estimate of each other's moral character: How is this circumstance to be reconciled with the progressive generation of love? We answer, By an association of ideas which is formed upon principles of physiognomy. Every passion and habitual disposition of mind gives a particular cast to the countenance, and is apt to discover itself in some feature of the face. This we learn by experience; and in time, without any effort of our own, the idea of each particular cast of countenance comes to be so closely associated in our minds with the internal disposition which it indicates, that the one can never afterwards be presented to our view without instantly suggesting the other to the imagination. (See METAPHYSICS and PHYSIOGNOMY). Hence it is that every man, who has been accustomed to make observations, naturally forms to himself, from the features and lineaments of a stranger's face, some opinion of his character and fortune. We are no sooner presented to a person for the first time, than we are immediately impressed with the idea of a proud, a reserved, an affable, or a good-natured man; and upon our going into a company of absolute strangers, our benevolence or aversion, our awe or contempt, rises instantly towards particular persons, before we have heard them speak a word, or know so much as their names or designations. The same thing happens when we are presented to the fair sex. If a woman, seen for the first time, have that particular cast of countenance, and that expression of features, to which we have associated notions of *gentleness*, *modesty*, and other female virtues, she instantly commands our esteem;

and if she have likewise so much *beauty* as to make her an object of particular *desire*, esteem and desire become suddenly combined; and that combination constitutes the affection of love. Such, too, is the nature of all mental associations, that each part of which they are composed adds strength and vividness to the other parts; so that, in the present instance, desire makes us imagine virtues in the woman which her countenance perhaps does not indicate; and the virtues which are there actually visible, make us apprehend her beauty as more perfect than it is.

The affection thus generated is more or less pure, and will be more or less permanent, according as the one or the other part of which it is compounded predominates. "Where desire of possession || prevails over || our esteem of the person and merits of the definable object, love loses its benevolent character: the appetite for gratification becomes ungovernable, and tends violently to its end, regardless of the misery that mult follow. In that state love is no longer a sweet agreeable affection; it becomes a selfish, painful passion, which, like hunger and thirst, produceth no happiness but in the instant of fruition; and when frustration is over, disgust and aversion generally succeed to desire. On the other hand, where esteem, founded on a virtuous character and gentle manners, prevails over animal desire, the lover would not for the world gratify his appetite at the expence of his mistress's honour or peace of mind. He wishes, indeed, for enjoyment; and to him enjoyment is more exquisite than to the mere sensual lover, because it unites sentiment with the gratification of sense; at the same time that, so far from being succeeded by disgust or aversion, it increases his benevolence to the woman, whose character and manners he esteems, and who has contributed so much to his pleasure. Benevolence to an individual, having a general end, admits of acts without number, and is seldom fully accomplished. Hence mutual love, which is composed chiefly of esteem and benevolence, can hardly be of a shorter duration than its objects. Frequent enjoyment endears such lovers to each other, and makes constancy a pleasure; and when the days of sensual enjoyment are over, esteem and benevolence will remain in the mind, making sweet, even in old age, the society of that pair, in whom are collected the affections of husband, wife, lover, friend, the tenderest affections of human nature."

From the whole of this investigation, we think it appears, that the affection between the sexes which deserves the name of *love*, is inseparably connected with virtue and delicacy; that a man of loose morals cannot be a faithful or a generous lover; that in the breast of him who has ranged from woman to woman for the mere gratification of his sensual appetite, desire mult have effaced all esteem for the female character; and that, therefore, the maxim too generally received, "that a reformed rake makes the best husband," has very seldom a chance to be true. We think it may likewise be inferred, that thousands fancy themselves in love who know not what love is, or how it is generated in the human breast: and therefore we beg leave to advise such of our readers as may imagine themselves to be in that state, to examine their own minds, with a view to discover, whether, if the objects of their love were old or ugly, they would still esteem

Love.

them for the virtues of their character, and the propriety of their manners. This is a question which deserves to be well weighed by the young and the amorous, who, in forming the matrimonial connection, are too often blindly impelled by mere animal desire inflamed by beauty. "It may indeed happen, after the pleasure of gratifying that desire is gone (and if not refined by esteem and benevolence, go it must with a swift pace), that a new bond of attachment may be formed upon more dignified and more lasting principles; but this is a dangerous experiment. Even supposing good sense, good temper, and internal worth of every sort, yet a new attachment upon such qualifications is rarely formed; because it commonly, or rather *always*, happens, that such qualifications, the only solid foundation of an indissoluble connection, if they did not originally make esteem predominate over animal desire, are afterwards rendered altogether invisible by satiety of enjoyment creating disgust."

Elements
of Criticism.

Love, in medicine. The symptoms produced by this passion as a disease, according to medical writers, are as follow: The eye-lids often twinkle; the eyes are hollow, and yet appear as if full with pleasure: the pulse is not peculiar to the passion, but the same with that which attends solicitude and care. When the object of this affection is thought of, particularly if the idea is sudden, the spirits are confused, the pulse changes, and its force and time are very variable: in some instances, the person is sad and watchful; in others, the person, not being conscious of his state, pines away, is slothful, and regardless of food; though the wife, when they find themselves in love, seek pleasant company and active entertainments. As the force of love prevails, sighs grow deeper; a tremor affects the heart and pulse; the countenance is alternately pale and red; the voice is suppressed in the fauces; the eyes grow dim; cold sweats break out; sleep absents itself, at least until the morning; the secretions become disturbed; and a loss of appetite, a hectic fever, melancholy, or perhaps madness, if not death, constitutes the sad catastrophe. On this subject the curious may consult *Egineta*, lib. iii. cap. 17. *Oribat.* Synop. lib. viii. cap. 9. or a treatise professedly written on love, as it is a distemper, by James Ferrard, Oxford, printed 1640.

The manner of the Greeks and Romans were similar to each other in the affairs of love. They generally made a discovery of their passion, by writing upon trees, walls, doors, &c. the name of their beloved. They usually decorated the door of their dulcinea with flowers and garlands, made libations of wine before their houses, sprinkling the posts with the same liquor, as if the object of their affection was a real goddess. For a man's garland to be untied, and for a woman to compose a garland, were held to be indubitable indications of their love.

When their love was without success, they used several arts to excite affection in the object of their desire. They had recourse to enchantresses, of whom the Thessalian were in the highest estimation.—The means made use of were most commonly philtres or love potions, the operation of which was violent and dangerous, and frequently deprived such as drank them of their reason. Some of the most remarkable ingre-

dients of which they were composed were these: the hippomanes, the jynx, insects bred from putrefaction, the fish remora, the lizard, brains of a calf, the hairs on the tip of a wolf's tail, his secret parts, the bones of the left side of a toad eaten with ants, the blood of doves, bones of snakes, feathers of screech-owls, twisted cords of wool in which a person had hanged himself, rags, torches, reliques, a net of swallows buried and famished in the earth, bones snatched from hungry bitches, the marrow of a boy famished in the midst of plenty, dried human liver; to these may be added several herbs growing out of putrid substances. Such were the ingredients that entered into the composition of that infernal draught a *love potion*.

But, besides the philtres, various other arts were used to excite love, in which the application of certain substances was to have a magical influence on the person against whom they levelled their skill. A hyena's udder worn under the left arm, they fancied would draw the affections of whatever woman they fixed their eyes upon. That species of olives called *πύρα*, and barley-bran made up into a paste, and thrown into the fire, they thought would excite the flame of love. Flour was used with the same intention. Burning laurel, and melting wax, were supposed to have the like effect. When one heart was to be hardened, and another mollified, clay and wax were exposed to the same fire together. Images of wax were frequently used, representing the persons on whom they wished to make an impression; and whatever was done to the substitute of wax, they imagined was felt by the person represented. Enchanted medicaments were often sprinkled on some part of the house where the person resided. Love-pledges were supposed to be of singular use and efficacy: these they placed under their threshold, to preserve the affections of the owner from wandering. Love-knots were of singular power, and the number three was particularly observed in all they did. But no good effect was expected, if the use of these things was not attended with charms or magical verses and forms of words. See *Magic*.

Having mentioned their arts of exciting love, it may not be amiss to take notice, that the ancients imagined, that love excited by magic might be allayed by more powerful spells and medicaments, or by applying to demons more powerful than those who had been concerned in raising that passion. But love inspired without magic had no cure; Apollo himself could find no remedy, but cried out

Hei mihi quod nullis amor est medicabilis herbis.

The antidotes against love were generally *agnus castus*, which has the power of weakening the generative faculty; sprinkling the dust in which a male had rolled herself; tying toads in the hide of a beast newly slain; applying amulets of minerals or herbs, which were supposed of great efficacy in other cases; and invoking the assistance of the infernal deities. Another cure for love was bathing in the waters of the river Sclemnus; to which we may add the lover's leap, or jumping down from the Leucadian promontory.

Love-Apple. See *Solanum*.

LOVENTINUM, or LUENTINUM, (anc. geog.) a town of the Demeta in Britain, near the mouth of the Tuerobis or Tyvi. Supposed to have been afterwards

Love,
Loventinum.

Loughbo-rough wards swallowed up by an earthquake, and to have flood where is now the lake called *Lin Suatan* in Brecknockshire.

Lough-neach. LOUGHBOROUGH, a town of Leicestershire in England, 110 miles from London. It is the second town in the county, and was in the Saxons time a royal village. Its market is on Thursday; and its fairs are on April 25th, May 28th, August 1st, and November 2d. It has a large church, and a free school; besides a charity school for 80 boys and another for 20 girls. It has been very much reduced by fires; but is still a very agreeable town, with rich meadow-ground, on the Fosse, which runs here almost parallel with the river Soar. The new canal has made the coal-trade here very extensive.

LOUGHBRICKLAND, a fair and post town of Ireland, situated in the county of Down, and province of Ulster, 58 miles from Dublin. The name signifies the lake of the *speckled trout*; and it was so called from a lake near it, which abounds with those fish. It consists of one broad street, at the end of which is the parish-church, said to have been built by Dr Taylor when bishop of Dromore, soon after the Restoration. The linen manufacture is carried on here very extensively; and the town is a great thoroughfare, the turnpike road from Dublin to Belfast passing through a red bog near it. The fairs are five in the year.

LOUGH-DERG, anciently *Dergabhan*, i. e. "the river of the woody morafs," from a river which issues out of this lake. This lough is situated in the county of Donegal and province of Ulster in Ireland, and is famous for having in it the island that contains St Patrick's purgatory, which is a narrow little cell, hewn out of the solid rock, in which a man could scarce stand upright.—There is also a lake of this name situated between the counties of Galway and Tipperary.

LOUGH-NEACH, a loch or lake of Ireland, situated in the counties of Armagh, Down, Derry, and Antrim, and province of Ulster. It is the largest in Europe, those of Ladoga and Onega in Russia, and that of Geneva in Switzerland, excepted; being 20 miles long and 15 broad. The area of this lake is computed to be 100,000 acres. It is remarkable for a healing virtue; and likewise for petrifying wood, which is not only found in the water but in the adjacent soil at a considerable depth. On its shores several beautiful gems have been discovered. Its ancient name was *Loch-neacha* or *Loch-Neach*, from *loch*, "a lake," and *Neach*, "wonderful, divine, or eminent." Its petrifying powers are not instantaneous, as several of the ancients have supposed, but require a long series of ages to bring them to perfection, and appear to be occasioned by a fine mud or sand, which insinuates itself into the pores of the wood, and which in process of time becomes hard like stone. On the borders of this lake is Shane's castle, the elegant seat of the right honourable John O'Neil. Dr Smyth seems to doubt whether the healing quality in this lake is not to be confined to one side of it, called the *fishing-bank*; and he informs us, that this virtue was discovered in the reign of Charles II. in the infancy of the son of one Mr Cunningham, who had an *evil* which run on him in eight or ten places; and notwithstanding all applications seemed incurable, at length

he was perfectly healed, after bathing in this lough about eight days. Hence that writer gives us another derivation of the name *Lochneach*, which (he says) seems to hint at this quality; *Neagh* or *Neat*, in Irish, signifying a sore or ulcer," which might not improbably be corrupted into *Neagh*; Hence he apprehends, this lake was remarked at a much earlier period for its healing property. As to its petrifying power, it is mentioned by Nennius, a writer of the 9th century, who says, "Eit aliud stagnum quod facit ligna durescere in lapides. Homines autem findunt ligna, et postquam formaverunt, projiciunt in stagnum, et manent in eo usque ad caput anni, et in capite anni lapidis invenitur, et vocatur stagnum *Loch-Eebach*." Lough-Neach gives title of baron to the family of *Skeffington*.

LOUGH-STRANGFORD, a lake of Ireland, situated in the county of Down and province of Ulster. It takes its present name from a small port-town called *Strangford*, seated on the west side of the narrow entrance into the sea. It was formerly known by the name of *Lough-Cone* or *Lough-Coyne*. It is a deep bay or inlet of the sea, about 17 miles long and four or five broad; it goes west as far as Downpatrick, and north as far as Comber and Newtown, and by computation covers 25,775 acres, Irish plantation measure. It abounds with excellent fish, particularly smelts; and off the bar there is a periodical herring fishery in or about August. The bar or entrance into this lough is about three miles below Strangford. There is a long rock at the entrance in the middle of the passage, dangerous to strangers on account of the current; yet there is a broad passage on either side, and deep water. The current here is very strong and rapid, running at the rate of six or seven miles an hour. There are but few vessels that go higher up than Strangford. A good many vessels bound up the channel put in here, if the wind is unfavourable to their passage. The islands in this lake are numerous; Doctor Boat enumerates them at 250. But from an actual survey, made at the time Dr Smyth wrote his history of that county, it appears, there are 54 islands small and great, known by particular names, and many others nameless; the contents of these 54 islands added together amount to 974 acres and an half. The great and profitable manufacture carried on in these islands, and the flat stony coasts surrounding the lake, is the burning of sea-weed into kelp, which employs a number of hands, and has been computed to produce to the several proprietors a neat profit of 1200 l. per annum and upwards. Four of the islands here are called *Swan islands*, from the number of swans that frequent them.

LOUIS, or *Knights of St Louis*, the name of a military order in France, instituted by Louis XIV. in 1693. Their colours are of a flame colour, and pass from left to right; the king is their grand master. There are in it eight great crosses, and 24 commanders; the number of knights is not limited. At the time of their institution, the king charged his revenue with a fund of 300,000 livres for the pensions of the commanders and knights.

LOUIS, *Lewis*, *Louis d'or*, or *Lewidore*, a French coin, first struck in 1640, under the reign of Louis XIII. and which has now a considerable currency. See *MONEY-TABLE*.

Louisiana
 Louvain.

LOUISIANA, a country in North-America, bounded on the south by the gulph of Mexico, on the east by the river Mississippi, on the west by New Mexico, and on the north by an unknown country. It extends from the 29th to the 40th degree of north latitude, and from about the 82th to the 96th or 97th degree west longitude from London. The climate of Louisiana varies according to the latitudes. The southern parts are not so hot as those parts of Africa which lie under the same parallel, and the northern parts are colder than the countries of Europe at the same distance from the pole; the causes of which are supposed to be the thick forests which over-run the country, and the great number of rivers; the former preventing the sun from heating the earth, and the latter supplying it with moist vapours; besides the cold winds which come from the north over vast tracts of land. They have bad weather; but it never lasts long, for the rain generally falls in storms and sudden showers; the air is wholesome, the inhabitants healthy, and they who are temperate live to a great old age. The country is extremely well watered; and almost all the rivers that run through it fall into the Mississippi, which discharges itself into the gulph of Florida.

LOUSE, in zoology. See **PEDICULUS** and **LICE**.

LOUSY DISEASE. See **MEDICINE-Index**.

LOUTH, a town of Lincolnshire in England, 156 miles from London. It is a town corporate; and one of the handsomest and gayest in the county, there being in it not only frequent assemblies, concerts, &c. but even masquerades. Here are several handsome houses. From hence there is a canal to the sea at Tilney, about eight miles. Besides a charity school for 40 children, it has a free school founded by Edward VI. with a large church, and a fine steeple, which some think is as high as Grantham spire, which is 288 feet high. Its markets are on Wednesday and Saturday, and its fairs on May 24th, and August 16th.

LOUTH, a county in the eastern part of Ireland, which extends in the form of a bow or half-moon, on the side of the ocean, being much longer than it is broad; it is bounded on the south and south-west by the county of East-Meath, on the north-west by Monaghan, on the north by Armagh, and on the north-east by the bay of Carlingford, which parts it from the county of Down: it is watered by several small rivers which fall into the sea; and its south frontiers are watered by the river Boyne. Its chief towns are Dundalk and Carlingford; unless we include Drogheda, a part whereof is in this county. It is the smallest county in the kingdom; but very fertile and pleasant, and abounding with many remains of antiquities, of which Mr Wright, in his *Louthiana*, has given a very ample description. It contains 111,180 Irish plantation acres, 50 parishes, 5 baronies, and 5 boroughs, and returns 10 members to parliament: it is about 22 miles long and 14 broad.

LOUTH, a town in the above county, having a yearly fair.

LOUVAIN, a city in the Austrian Netherlands, in the province of Brabant, pleasantly seated on the river Dyle, in a plentiful and agreeable country. The walls are about eight or nine miles in circumference; but they include several fields and vineyards. The castle stands

on a high hill, surrounded with fine gardens, and has a charming prospect all over the country: This town contains nine market places, 14 water-mills, 126 streets, 16 stone bridges, and several handsome palaces. The town-house is a venerable old building, adorned with statues on the outside; and the churches are very handsome, particularly the collegiate church of St Peter, but the principal ornament is the university, founded only in 1426 by John IV. duke of Brabant, with the concurrence of Pope Martin V. It contains about 40 colleges, four of which are called *Pedagogia*. There is in the number also an English college of friars-preachers, which owes its establishment to the liberalities of Cardinal Philip Howard, brother to the duke of Norfolk, who, before he was raised to the purple, had been private chaplain to Queen Catherine, consort to Charles II. The Irish have likewise a seminary, erected in part under the care of Eugenius Mattheus, titular archbishop of Dublin, anno 1623, which receives its appointments from the Propaganda at Rome. Besides the above, there are two convents for the Irish, one of Recollets and the other of Dominicans, where divinity and the Mathesis are taught. In the last century the number of scholars exceeded 4000, but in the year 1743 the inhabitants amounted to 12,000, including 2000 students only.—At the beginning of the 14th century, under John III. it flourished considerably in the manufacture of woollen cloth: 400 houses were then occupied by substantial clothiers, who gave employment to an incredible number of weavers, so great it is said, that a bell was rung to prevent any injuries which the children in the street might receive from the crowd and hurry on their returning from work. In 1382, these weavers, however, took up arms, and rebelled against their sovereign Prince Wenceslaus, throwing from the windows of the Town-hall 17 of the aldermen and counsellors, and afterwards proceeded to lay waste great part of Brabant: but being besieged and reduced to great extremities, they submissively implored his clemency: which was granted after the execution of some of the principal ringleaders. The weavers, the chief instigators to this revolt, were banished, the greater part of whom took refuge in England; where they first introduced, or at least augmented very much, the woollen manufacture. The town, by this circumstance, being almost depopulated, the university was established to supply in some measure the loss of the rebellious clothiers. Since that time the manufacture gradually declined, no cloth of any account being made there at present. This impolitic step of the Duke Wenceslaus sent treasures to England, through the hands of those exiled people; an important lesson to governors, that they should deal with great precaution respecting such useful members of the community. Upon the ruins of these looms was formed the cloth manufacture of Limbourg, which is carried on with good advantage to this day. There is yet standing at Louvain part of the old drapers-hall, now converted into four public schools, where lectures in divinity, philosophy, law, and physic, are given, and the public ads are made. Adjoining to the schools is the university library, which altogether compose a large pile of building. Over the door of the chief entrance we read these words, *Sapientia adificavit huius domum*. The principal church is collegiate, dedicated to

Louvain.

Louys,
Low-bell.

St Peter, which had formerly three very large towers with elevated spires, one considerably higher than the two collaterals; these were blown down in the year recorded by this chronogram, *oMula CaDVnt*. From the name of this church the burghers have acquired the nick-name of *Petermen*, whose ancestors having clothed the back by a noble woollen manufacture, the modern *Petermen* now compose an ignoble mixture for the belly, called after them, *Peterman beer*, a sort of whitish muddy ale, which they notwithstanding send in large quantities to all parts of the country, as well as to Holland, by the canals. Louvain was anciently the capital of the province, long before Bruxelles had any claim to that title. E. Long. 4. 40. N. Lat. 51. 12.

LOUYS, or LOUIS, (John), an engraver of considerable eminence, who flourished about the middle of the 16th century. According to Baſan, he was a native of Flanders. He learned the art of engraving from Peter Soutman, at the time that Suyderhoef studied under the same master; and his usual style of engraving bears some resemblance to that of his master's. One of his best prints is, Diana, with her nymphs, reposing after the chase; a middling-sized plate, lengthwise, from Rubens.

LOW-BELL, in birding, a name given to a bell, by means of which they take birds in the night, in open champaign countries, and among stubble, in October. The method is to go out about nine o'clock at night in a still evening, when the air is mild and the fow does not shine. The low-bell should be of a deep and hollow sound, and of such a size that a man may conveniently carry it in one hand. The person who carries it is to make it toll all the way he goes, as nearly as may be, in that manner in which the bell on the neck of a sheep tolls as it goes on and feeds. There must also be a box made like a large lantern, about a foot square, and lined with tin, but with one side open. Two or three great lights are to be set in this; and the box is to be fixed to the person's breast, with the open side forwards, so that the light may be cast forward to a great distance. It will spread as it goes out of the box; and will distinctly show to the person that carries it whatever there is in the large space of ground over which it extends, and consequently all the birds that roost upon the ground. Two persons must follow him who carries the box and bell, one on each side, so as not to be within the reach of the light to show themselves. Each of these is to have a hand-net of about three or four feet square, fastened to a long stick or pole; and on whichever side any bird is seen at roost, the person who is nearest is to lay his net over it, and take it with as little noise as possible. When the net is over the bird, the person who laid it is not to be in a hurry to take the bird, but must stay till he who carries the light is got beyond it, that the motions may not be discovered. The blaze of the light and the noise of the bell terrify and amaze the birds in such a manner that they remain still to be taken; but the people who are about the work must keep the greatest quiet and stillness that may be.

Some people are fond of going on this scheme alone. The person then fixes the light box to his breast and carries the bell in one hand and the net in the other; the net in this case may be somewhat smaller, and the handle shorter. When more than

one are out at a time, it is always proper to carry a gun; as it is no uncommon thing to spy a hare when on this expedition.

LOW (EAST), a town of Cornwall in England, 231 miles from London, in the post-road from Plymouth. It is an ancient borough by precription, made a corporation by charter of queen Elizabeth, consisting of nine burgesses (one of whom is yearly chosen the mayor), a recorder, aldermen, &c.; and the mayor, magistrates, and freemen, who are about 68, choose the members of parliament. This being a manor of the duchy of Cornwall, was settled by king William on lord Somers, and is now held by the corporation at the fee-farm rent of 20s. a-year. It is seated pretty commodiously on a creek of the sea, over which there is a large stone bridge, supported by 15 arches, which leads to *West Low*, standing between two hills. The chief benefit which the inhabitants have is in their fishery. Here is a battery of four guns, and a small chapel. Its market is on Saturday, and it has two fairs in the year.

Low (West), called also *Port-Pigbam*, a town of Cornwall, divided from East Low by a stone bridge of 15 arches over the river Low, from whence both towns receive their name, as the river does from the lowness of its current between its high banks. The corporation, by charter of queen Elizabeth, consists of 12 burgesses, one of whom is annually chosen mayor, and, with the other burgesses, has power to choose a steward. Its members, whom it has sent to parliament ever since the 6th of Edward VI. are elected by the corporation and freemen, who are about 60. There was a chapel of ease here in the reign of Henry VIII. which was afterwards converted into a town-hall; and the town lying in the parish of Taland, the people go thither to church. The market is on Saturday, and fair on April 25. There is a pretty little harbour here; near the mouth of which is a small island called St George's, which abounds with sea-peas. The river here is navigable for vessels of 100 tons.

LOWER (Richard), an eminent English physician in the 17th century, was born in Cornwall, and educated at Westminster-school and Oxford. He entered on the physic line; and practised under Dr Thomas Willis, whom he instructed in some parts of anatomy, especially when the latter was writing his *Cerebri anatome*. He, with Dr Willis, in 1674, discovered the medicinal waters at Ashup in Northamptonshire; which, upon their recommendations, became very much frequented. In 1666 he followed Dr Willis to London; practised physic under him; and became fellow of the royal society, and of the college of physicians. In 1669 he published his *Traictatus de corde*; and, after the death of Dr Willis in 1675, he was esteemed the most eminent physician in London. Upon the breaking out of the Popish plot in 1678, says Mr Wood in his *Athena Oxoniensis*, he clofed with the Whigs, supposing that party would carry all before them; but, being mistaken, he lost his credit and practice. He died in 1691.

LOWERING, among distillers, a term used to express the debasing the strength of any spirituous liquor, by mixing water with it. The standard and marketable price of these liquors is fixed in regard to

Low
Lowering.

Lowth.

a certain strength in them called *proof*; this is that strength which makes them, when shaken in a phial or poured from on high into a glass, retain a froth or crown of bubbles for some time. In this state, spirits consist of about half pure or totally inflammable spirit, and half water; and if any foreign or home spirits are to be exposed to sale, and are found to have that proof wanting, scarce any body will buy it till it has been distilled again and brought to that strength; and if it is above that strength, the proprietor usually adds water to it to bring it down to that standard. See the article *PROOF*.

There is another kind of lowering among the retailers of spirituous liquors to the vulgar, by reducing it under the standard proof. Whoever has the art of doing this without destroying the bubble proof, which is easily done by means of some addition that gives a greater tenacity to the parts of the spirits, will deceive all that judge by this proof alone. In this case, the best way to judge of liquors is by the eye and tongue, and especially by the instrument called *HYDROMETER*.

LOWTH (William), D.D. a learned divine, born at London in 1661, was the son of an apothecary, and took his degrees at Oxford. His eminent worth and learning recommended him to Dr Mew bishop of Winchester, who made him his chaplain, gave him two livings in Hampshire, and conferred on him a prebend in the cathedral of Winchester. He acquired an unusual share of critical learning. Thus situated in life, the labours of Mr Lowth appear to have been strictly confined within the limits of his own province, and applied solely to the peculiar duties of his function; yet, in order that he might acquit himself the better in theology, he had purified his studies with a more general and extensive view. Few were more deeply versed in critical learning; there being scarcely any ancient author, Greek or Latin, profane or ecclesiastical, especially the latter, but what he had read with accuracy, constantly accompanying his reading with critical and philological remarks. Of his collections in this way he was upon all occasions very communicative. Hence his notes on *Clemens Alexandrinus*, which are to be met with in Potter's edition of that father. Hence his remarks on *Josephus*, communicated to Hudson for his edition, and acknowledged in the preface: as also those larger and more numerous annotations on the Ecclesiastical Historians, inserted in *Reading's* edition of them at Cambridge. The author of *Bibliotheca Biblica* was indebted to him for the same kind of assistance. Chandler, late bishop of Durham, while engaged in his "Defence of Christianity, from the Prophecies of the Old Testament, against the Discourse of the Grounds and Reasons of the Christian Religion," and in his "Vindication of the Defence, in answer to The Scheme of Literal Prophecy considered," held a constant correspondence with him, and consulted him upon many difficulties that occurred in the course of that work. The most valuable part of his character was that which least appeared in the eyes of the world, the private and retired part, that of the good Christian and the useful parish-priest. His piety, his diligence, his hospitality and beneficence, rendered his life highly exemplary, and greatly enforced his public exhortations.

Lowth.

He married Margaret, daughter of Robert Pitt, Esq; of Blandford, by whom he had two sons and three daughters. (see the next article). He died in 1732, and was buried by his own orders in the church-yard at Buriton. He published, 1. A vindication of the divine authority and inspiration of the Old and New Testaments; 2. Directions for the profitable reading of the Holy Scripture; 3. Commentaries on the prophecies; and other works.

LOWTH (Robert), D.D. second son of the preceding Dr William Lowth, and bishop successively of St David's, Oxford, and London, was born on the 29th of November 1710, probably at Buriton in the county of Hants. He received the rudiments of his education in Winchester college, where his school exercises were distinguished by uncommon elegance; and having resided the requisite number of years in that seminary, in 1730 he succeeded on the foundation at New College, Oxford. He took the degree of M. A. June 8. 1737. Though his abilities must have been known to those with whom he was connected, he was not forward to appear before the world as a writer. At Oxford he continued many years improving his talents, with little notice from the great, and with preference so small as to have at present escaped the distinct recollection of some of his contemporaries.

He was not, however, suffered to languish for ever in obscurity. His genius and his learning forced themselves upon the notice of the illustrious society of which he was a member; and he was placed in a station where he was eminently qualified to shine. In 1741 he was elected by the university to the professorship of poetry, re-elected in 1743, and whilst he held that office he read his admirable lectures *De sacra poesi Hebraeorum*. In 1744 bishop Hoadley collated him to the rectory of Ovington in the county of Hants; added to it, nine years afterwards, the rectory of East Weedhay in the same county; and in the interim raised him to the dignity of archdeacon of Winchester. These repeated favours he some years afterwards acknowledged in the following manly and respectful terms of gratitude: "This address, My Lord, is not more necessary on account of the subject, than it is in respect of the author. Your Lordship, unsolicited and unasked, called him from one of those colleges to a station of the first dignity in your diocese, and took the earliest opportunity of accumulating your favour upon him, and of adding to that dignity a suitable support. These obligations he is now the more ready thus publicly to acknowledge, as he is removed out of the reach of further favours of the like kind. And though he hath relinquished the advantages so generously conferred on him, yet he shall always esteem himself highly honoured in having once enjoyed the patronage of the great advocate of civil and religious liberty."

On the 8th of July 1754 the university of Oxford conferred upon him the degree of D. D. by diploma; an honour which, as it is never granted but to distinguished merit, was probably conferred on Mr Lowth in consequence of his prelections on the Hebrew poetry, which had then been lately published. Having in 1749 travelled with Lord George and Lord Frederick Cavendish, he had a claim upon the patronage of the

Lowth.
